CONTENT

Warning: This material is still (heavily) under construction and might change throughout the course!

You can help improving the course and let me know about any errors and inconsistencies that you find or suggest other ways of improving the course.

Welcome!

These pages present the content of the course "Introduction to Musical Corpus Studies" at the Institute of Musicology, given at University of Cologne in Fall 2020.

In the last two decades *Musical Corpus Studies* evolved from a niche discipline into a veritable research area. The growing availability of digital and digitized musical data as well as the application and development of modern methodologies from computer science, machine learning, and data science cast new light on old musicological questions and generate entirely novel approaches to empirical music research.

Moreover, the general methodological and epistemological approach of Musical Corpus Studies allows to transcend traditional intra-musicological boundaries between its sub-disciplintes (historical/systematic/ethnological/...) without sacrificing the respective specific viewpoints and perspectives.

This course offers a fundamental and practical introduction into these topics. It demonstrates, explores, and critically reflects central thematic areas and methods by means of a number of case studies. In the engagement with these topics the course also introduces elementary methods from natural language and music processing, as well as statistics, data analysis and visualization.

The course is aimed at students at the undergraduate level who have little or no empirical background and are curious about quantitative approaches to musicology.

CHAPTER

ONE

ORGANIZATION

1.1 About this course

This course aims at providing an example-based introduction to the rapidly developing field of Musical Corpus Studies (MCS). Introducing a field that relies equally on musicological domain knowledge and skills in computational and statistical methods faces obvious challenges: while most people interested in this field come with a background in either area, few people are versed in both, and it can take years to bridge the musicological-computational gap.

In particular, systematic introductions to programming or specific musicological topics can be at times quite arduous, even boring, because it takes a long time to proceed from learning basic concepts to acually interesting problems. The problems and "toy examples" that are presented to introduce the basic concepts are necessarily remote from real-world applications and challenging research problems.

This course takes an alternative route. It does not start with an introduction to the programming language Python (which will be used throughout to carry out the computational analyses) but rather showcases a number of recent corpus studies that take on musicological research questions. The focus thus lies in understanding how aspects of music can be studied with computational methods and by analyzing musical corpora.

If this sparks your interest, it will be much easier to pick up the basics for yourself, knowing what they are *for* and being motivated intrinsically. If you are not particularly interested in doing this kind of work yourself, you will still see a broad range of applications that are much more useful to you than learning (or not learning) programming basics.

1.2 Overview

This year's course takes place on two weekends (13-14 November and 11-12 December 2020), comprising twelve sessions in total. The topics cover a broad range of musicological topics, from folk melodies and Jazz solos, over harmonies in Beethoven's string quartets and 20th century Pop music, to Renaissance candences and metric patterns in Malian drum music (see Table 1.2).

No.	Date	Time	Topics
1	Fr., 13.11.2020	16:00-17:20 Uhr	Introduction / Background
2		17:40-19:00 Uhr	Melody I: Folk song melodies, notes, form
3	Sa., 14.11.2020	09:00-10:20 Uhr	Melody II: The melodic arc, intervals
4		10:40-12:00 Uhr	Melody III: Jazz solos
		12:00-13:00 Uhr	*Lunch Break*
5		13:00-14:20 Uhr	Group work
6		14:40-16:00 Uhr	Beethoven's string quartets
7	Fr., 11.12.2020	16:00-17:20 Uhr	Cadences in Renaissance polyphony (guest: Richard Freedman)
8		17:40-19:00 Uhr	
9	Sa., 12.12.2020	09:00-10:20 Uhr	Rhythm & Meter: Malian percussion music
10		10:40-12:00 Uhr	Timbre: Electronic Music 1950-1990
		12:00-13:00 Uhr	*Lunch Break*
11		13:00-14:20 Uhr	Group work
12		14:40-16:00 Uhr	Recapitulation and conclusion

1.3 Credits

Active participation in this course is compensated with 3 credit points (CPs), equivalent to a work load of 90 hours. These are distributed as follows: 24 SWS (à 45 minutes) are allocated to presence in the block seminar. Additionally, 24 SWS are dedicated to the preparation and follow-up of the material. The remainder of 42 SWS goes to the reading of the relevant literature.

1.4 Deliverables and learning objectives

Apart from attending and following the presentations by the lecturer, course work consists of three main parts: preparing the relevant literature (reading), completing the assigned exercises (group work), and critically engaging with the course materials in the form of a report written together with your group (report).

These deliverables will broaden your knowledge and understanding of current musicological research, enhance your organizational and social skills, and help you to develop efficient work-load management strategies. Finally, compiling a report will advance your communication and writing abilities.

Reading

For each session, the relevant literature is cited in the text and provided on ILIAS. Careful preparation of the reading material is required in order to be able to follow the content of the course. Because the course will mainly talk about methods and general points of musical corpus research, the content (and musical topic) will mainly be introduced by the literature.

I am aware that the reading workload is relatively high since the course will be taught as a block seminar and doesn't spread out over the entire semester. I hope that the fact that the course is finished before the end of the year compensates for this.

Group work

At the beginning of the course, you will be randomly assigned to a group. Together with your group (which will stay fixed for the entire semester), you will work on a number of exercises during the course, e.g. in Zoom breakout rooms. You will collaborate on specific tasks related to the topic at hand, discuss methodological questions, and help each other in the understanding of some of the concepts that are introduced in the course.

Report

After the course has ended, your group will be randomly assigned a course topic (one of the twelve sessions in Table 1.2). It is your task to write a report on this theme. The should be 6–8 pages long.

Questions that you could address are: What did you learn? Which concepts are not clear? Which methods did you (not) understand? What is missing? How can the textual descriptions be improved? Who in your group did what? Was the presentation of the material adequate? If not, what was missing? Please also write about the organization of your group, challenges and benefits.

Recommended structure for the report

1. **Introduction:** general description and summary of the course and your assigned session in particular.
2. **Discussion:** summarize the main discussion, open questions, and how you would continue this line or research.
3. **Issues:** describe in detail what was crucial for your understanding of the topic, what was missing, etc.
4. **Various:** anything that you would like to write in the report
5. **Author contributions:** describe briefly how each of you specifically contributed to the report.

Important: Submit your report by **31 January 2021, 23:59h** to fabian.moss@epfl.ch as a single PDF file per group, named *intro_corpusmus_<group_number>.pdf*, e.g. *intro_corpusmus_1.pdf*.

THREE

MELODIES IN FOLK SONGS

On Jupyter Hub, change the kernel to Python 3.7!

[1]:
```
import pandas as pd
import music21 as m21
import numpy as np
import statsmodels.api as sm

import matplotlib.pyplot as plt
import matplotlib as mpl

import seaborn as sns
sns.set_context("notebook")
```

[2]:
```
## Tragen Sie hier bitte Ihren username ein:
# USERNAME = "fmoss"

## for jupyter hubs
# %env QT_QPA_PLATFORM=offscreen
# # new user, create music21 environment variables.
# m21.environment.set('musicxmlPath', value='/usr/bin/mscore')
# m21.environment.set('musescoreDirectPNGPath', value='/usr/bin/mscore')
# m21.environment.set('graphicsPath', value=f'/home/{USERNAME}') # change accordingly␣
↪for your own username!
```

3.1 The *Essen Folksong Collection*

In this session, we work with a corpus of melodies, the *Essen Folksong Collection* (EFC). There are several ways to access this corpus, for example through the interface provided by the Center for Computer Assisted Research in the Humanities (CCARH) at Stanford University: http://essen.themefinder.org/ or via http://kern.ccarh.org/browse?l=essen.

A more convenient way to work with the pieces is by using the Python library `music21`. This library was developed and is maintaned my Mike Cuthbert at the MIT and is the most popular library for the computational analysis of symbolic music (i.e. scores). You can find its documentation here: http://web.mit.edu/music21/

However, using `music21` requires some training and getting used to its particular API (the way how to interact with its functions). We will not get into too many details here but rather showcase how it can be used for our purposes.

The first thing we do is to load the entire EFC and store it in a variable named `corpora`.

[3]:
```
# load corpus
corpora = m21.corpus.getComposer('essenFolksong')
```

Calling the variable `corpora` shows that it consists of a list of file paths. Using the `len()` function, we can find out how many corpora are stored in the variable `corpora`.

```
[4]: len(corpora)
```

```
[4]: 31
```

We can also directly call the variable `corpora` to see what it contains:

```
[5]: corpora
```

```
[5]: [WindowsPath('C:/Users/fabianmoss/anaconda3/Lib/site-packages/music21/corpus/
↪essenFolksong/altdeu10.abc'),
 WindowsPath('C:/Users/fabianmoss/anaconda3/Lib/site-packages/music21/corpus/
↪essenFolksong/altdeu20.abc'),
 WindowsPath('C:/Users/fabianmoss/anaconda3/Lib/site-packages/music21/corpus/
↪essenFolksong/ballad10.abc'),
 WindowsPath('C:/Users/fabianmoss/anaconda3/Lib/site-packages/music21/corpus/
↪essenFolksong/ballad20.abc'),
 WindowsPath('C:/Users/fabianmoss/anaconda3/Lib/site-packages/music21/corpus/
↪essenFolksong/ballad30.abc'),
 WindowsPath('C:/Users/fabianmoss/anaconda3/Lib/site-packages/music21/corpus/
↪essenFolksong/ballad40.abc'),
 WindowsPath('C:/Users/fabianmoss/anaconda3/Lib/site-packages/music21/corpus/
↪essenFolksong/ballad50.abc'),
 WindowsPath('C:/Users/fabianmoss/anaconda3/Lib/site-packages/music21/corpus/
↪essenFolksong/ballad60.abc'),
 WindowsPath('C:/Users/fabianmoss/anaconda3/Lib/site-packages/music21/corpus/
↪essenFolksong/ballad70.abc'),
 WindowsPath('C:/Users/fabianmoss/anaconda3/Lib/site-packages/music21/corpus/
↪essenFolksong/ballad80.abc'),
 WindowsPath('C:/Users/fabianmoss/anaconda3/Lib/site-packages/music21/corpus/
↪essenFolksong/boehme10.abc'),

 WindowsPath('C:/Users/fabianmoss/anaconda3/Lib/site-packages/music21/corpus/
↪essenFolksong/irl.abc'),
 WindowsPath('C:/Users/fabianmoss/anaconda3/Lib/site-packages/music21/corpus/
↪essenFolksong/kinder0.abc'),
 WindowsPath('C:/Users/fabianmoss/anaconda3/Lib/site-packages/music21/corpus/
↪essenFolksong/lot.abc'),
```

(continues on next page)

(continued from previous page)

```
 WindowsPath('C:/Users/fabianmoss/anaconda3/Lib/site-packages/music21/corpus/
↪essenFolksong/lux.abc'),
 WindowsPath('C:/Users/fabianmoss/anaconda3/Lib/site-packages/music21/corpus/
↪essenFolksong/test0.abc'),
 WindowsPath('C:/Users/fabianmoss/anaconda3/Lib/site-packages/music21/corpus/
↪essenFolksong/test1.abc'),
 WindowsPath('C:/Users/fabianmoss/anaconda3/Lib/site-packages/music21/corpus/
↪essenFolksong/testd.abc'),
 WindowsPath('C:/Users/fabianmoss/anaconda3/Lib/site-packages/music21/corpus/
↪essenFolksong/teste.abc'),
 WindowsPath('C:/Users/fabianmoss/anaconda3/Lib/site-packages/music21/corpus/
↪essenFolksong/variant0.abc'),
 WindowsPath('C:/Users/fabianmoss/anaconda3/Lib/site-packages/music21/corpus/
↪essenFolksong/zuccal0.abc')]
```

The variable `corpora` is a list of file paths, each of which points to a corpus in this collection. Note that the location depends on the location where `music21` is installed. If you would do this on your own computer, you would see different paths. The file names at the end of the file paths indicate what they contain, e.g. `altdeu10.abc` contains old German folksongs, `boehme10.abc` contains Czech folksongs, and `han1.abc` contains Chinese folksongs.

The `.abc` file ending refers to the ABC notation for encoding melodies. You find more information about the ABC encoding here: http://abcnotation.com/

For example, a song could be encoded like this:

[6]:
```
example_song = """
X:1
T:Speed the Plough
M:4/4
C:Trad.
K:G
|:GABc dedB|dedB dedB|c2ec B2dB|c2A2 A2BA|
  GABc dedB|dedB dedB|c2ec B2dB|A2F2 G4:|
|:g2gf gdBd|g2f2 e2d2|c2ec B2dB|c2A2 A2df|
  g2gf g2Bd|g2f2 e2d2|c2ec B2dB|A2F2 G4:|
"""
```

The tripple quotes (`"""`) surrounding the ABC notation are used by Python to store multi-line text.

What can we already understand from this encoding?

`music21` can load this string and display a graphical output of the score. This is done by a **parser**. A parser is a program that reads a file and produces a structured output.

[7]:
```
parsed_example_song = m21.converter.parse(example_song)
```

We did not need to give it the entire string again because we have already saved it in the `example_song` variable. The purpose of variables is that you can refer to them later in your code without explicitly needing to state its value.

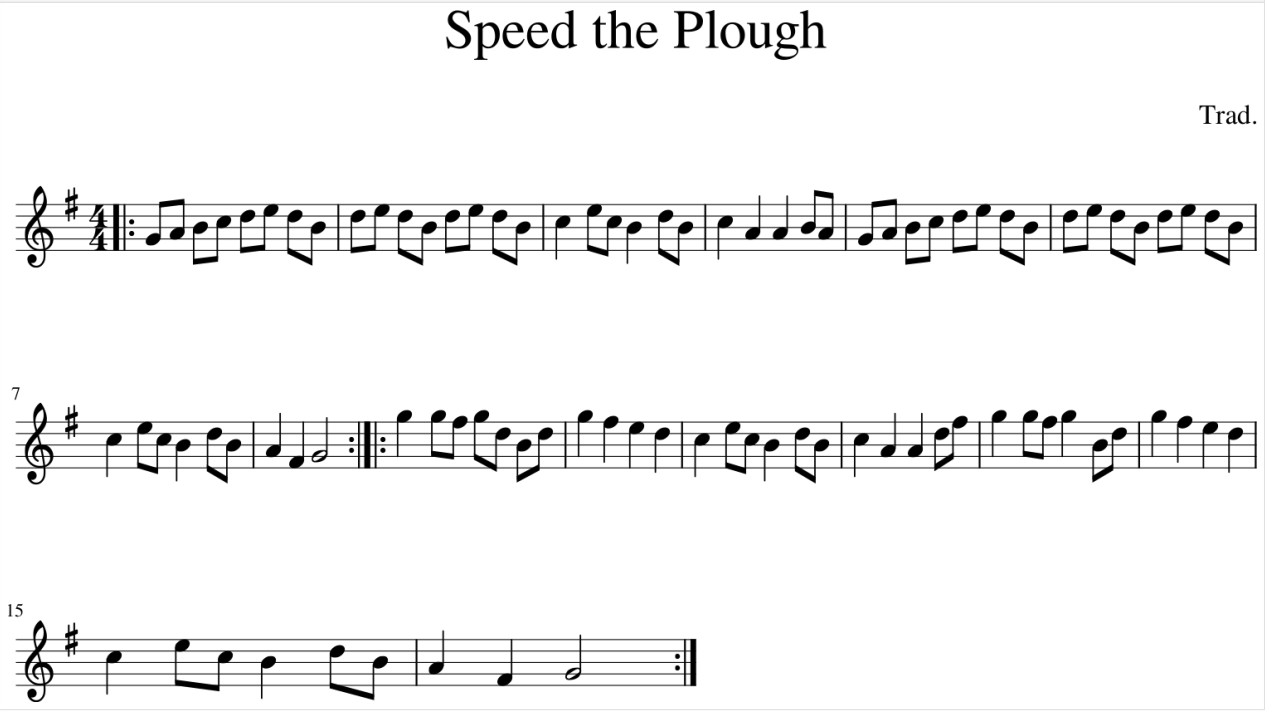
Calling the variable `parsed_example_song` now, however, does not really help us here...

[8]:
```
parsed_example_song
```

[8]:
```
<music21.stream.Score 0x1898a474340>
```

It returns a somewhat cryptic statement that says that the variable countains a `music21.stream.Score` object. Understanding the internal organization of `music21` goes beyond this class. For us, it is suffient to know that these objects have certain associated functions, called **methods**, that we can use on them. To look at the score of this example song, we use the method `.show()`.

[9]:
```
parsed_example_song.show()
```



Voilà, this is much better! Now, let us compare the score output to the ABC encoding of the song:

[10]:
```
print(example_song)
```

```
X:1
T:Speed the Plough
M:4/4
C:Trad.
K:G
|:GABc dedB|dedB dedB|c2ec B2dB|c2A2 A2BA|
  GABc dedB|dedB dedB|c2ec B2dB|A2F2 G4:|
|:g2gf gdBd|g2f2 e2d2|c2ec B2dB|c2A2 A2df|
  g2gf g2Bd|g2f2 e2d2|c2ec B2dB|A2F2 G4:|
```

Now the ABC notation makes already more sense. `T:Speed the Ploug` stands for the title, `M:4/4` for the meter, and `K:G` for the key of the song. The ABC documentation tells us that `X:1` encodes just a reference number, in case multiple pieces are stored in the same file (as in our case in the variable `corpora`, remember?). And the lines at the bottom encode the proper melody, where the letters represent note names that are organized into bars with or without repetition signs.

`music21` even gives us the option to listen to the song if we path the `midi` argument to the `.show()` method:

[11]:
```
parsed_example_song.show("midi")
```

```
<IPython.core.display.HTML object>
```

Now, what happens if we try to parse one of the corpora in the EFC? We can select a specific corpus by its **index** in the list. Python starts counting at 0, so the first file in the list corresponds to

```
[12]: corpora[0]
```

```
[12]: WindowsPath('C:/Users/fabianmoss/anaconda3/Lib/site-packages/music21/corpus/
      ↪essenFolksong/altdeu10.abc')
```

As you can see, this is just the first file path in the variable `corpora`. Let's try to parse it!

```
[13]: first_corpus = m21.converter.parse(corpora[0])
```

Looking at the new variable `first_corpus` shows a difference to the example song before; we don't have a `music21.stream.Score` object but a `music21.stream.Opus` object.

```
[14]: first_corpus
```

```
[14]: <music21.stream.Opus 0x1898b5ff4c0>
```

If we would call the `.show()` method on `first_corpus`, we would see the scores of all pieces that are in this particular corpus. But we don't know how many these are. It there are only three songs, it would not be a problem, but if there were thousands of songs, it could take a very long time to parse and display them all. Fortunately, all pieces in the collection have the `X:n` line that we saw above, so that we can directly reference them. With which number would we have to replace `n` if we wanted to look at the 7tst piece? Remember that Python starts counting at 0.

```
[15]: first_corpus[70].show()
```

A A B A'

```
[16]: first_corpus[70].show("midi")
```

```
<IPython.core.display.HTML object>
```

We have seen that we can select items from lists by **indexing** them, `list[i]`. We can get ranges of lists by using the `:` character. For example, `list[:10]` shows the first ten elements, `list[10:]` shows everything after the ninth element, and `list[3:6]` shows elements 3, 4, and 5 (not 6!) of the list.

3.2 Comparing songs

Looking at individual songs is interesting for music analysis but for that the computational approach is not really necessary. We could as easily do the same by just looking at a book of scores. The power of computational methods becomes clearer when we start comparing different songs, potentially in a large number.

To facilitate this comparison, we will first load all songs in all corpora of the EFC into a single list, called `songs` (this might take a couple of minutes).

[17]:
```
songs = [s for i in range(len(corpora)) for s in m21.converter.parse(corpora[i]) ]
```

This looks a bit complicated but all it does is to go through all corpora and extract all songs into a new list. The way we did it is called **list comprehension** in Python. It is not important if you don't understand this now but feel free to look it up!

Using the `len()` function again, we see how many songs we have in total.

[18]:
```
len(songs)
```

[18]:
```
8514
```

We can now use the list `songs` to compare two different songs. Again, we load the 71st song of the first corpus and store it now in a variable `german_song`, and we load chinese song with index 6200 into the variable `chinese_song`.

[19]:
```
german_song = songs[70]
chinese_song = songs[6200]
```

It is easy to display these songs now:

[20]:
```
german_song.show()
```

[21]:
```
chinese_song.show()
```

[22]:
```
chinese_song.show("midi")
```
```
<IPython.core.display.HTML object>
```

Analysis of songs...

3.3 Computational analysis

We now go on to a computational analysis of these two and all the other songs. Specifically, we wil compare their **melodic profiles**. To make things a bit simpler, we will just look at the notes.

A note can be easily represented as a pair of **pitch** (its height) and its **duration**. For example, the first note of the *Die plappernden Junggesellen* could be represented as `(D4, 1/4)`; it is a quarter note on the pitch D4 (the 4 indicates the octave in which the note is).

Another way to represent the pitch of notes is using **MIDI numbers**. MIDI stands for *Musical Instrument Digital Interface* and was developed for the communication between different electronic instruments such as keyboards. In MIDI, each note is simply associated with a number:

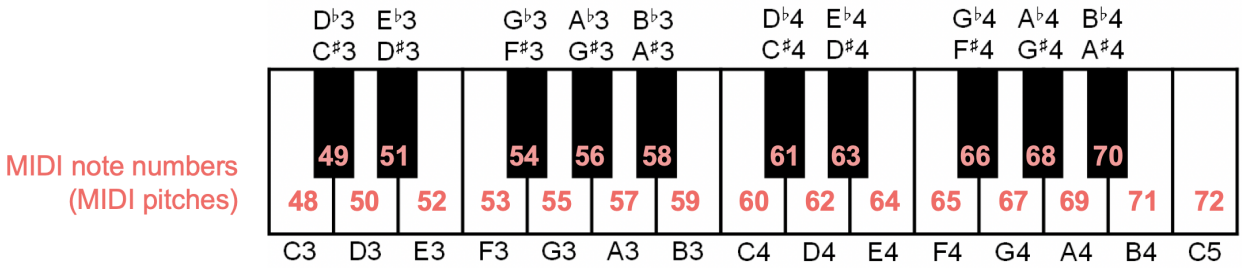


Image from https://www.audiolabs-erlangen.de/resources/MIR/FMP/C1/C1S2_MIDI.html.

We can see that D4 is associated with the number 62. The second note, the G4, is associated with 62+5=67 because G is five semitones above D.

To make it easier to work with pieces in this way, we define a **function** that gives us a list of notes for each piece.

[23]:
```
def notelist(piece):
    """
    This function takes a song as input and returns a list of (pitch, duration) pairs,
    where the duration is given in quarter notes.
```

(continues on next page)

(continued from previous page)

```
    """

    df = pd.DataFrame([ (note.pitch.midi, note.quarterLength) for note in piece.flat.
↪notes ], columns=["MIDI Pitch", "Duration"])
    df["Onset"] = df["Duration"].cumsum()

    return df
```

Note that the duration of a note is given in quarter notes, i.e. a quarter note has a duration of 1, a half note has a duration of 2, and an eighth note has a duration of 0.5.

Let's display the first phrase (the first eight notes) of the German song:

[24]:
```
notelist(german_song)[:8]
```

[24]:

	MIDI Pitch	Duration	Onset
0	62	1.0	1.0
1	67	2.0	3.0
2	71	2.0	5.0
3	74	3.0	8.0
4	72	1.0	9.0
5	71	2.0	11.0
6	69	2.0	13.0
7	67	2.0	15.0

Note that we added another column, "Onset". What does it represent?

This allows us now to look at the **melodic profile** of a particular song.

[25]:
```
def plot_melodic_profile(notelist, ax=None, c=None, mean=False, Z=False,␣
↪sections=False, standardized=False):

    if ax == None:
        ax = plt.gca()

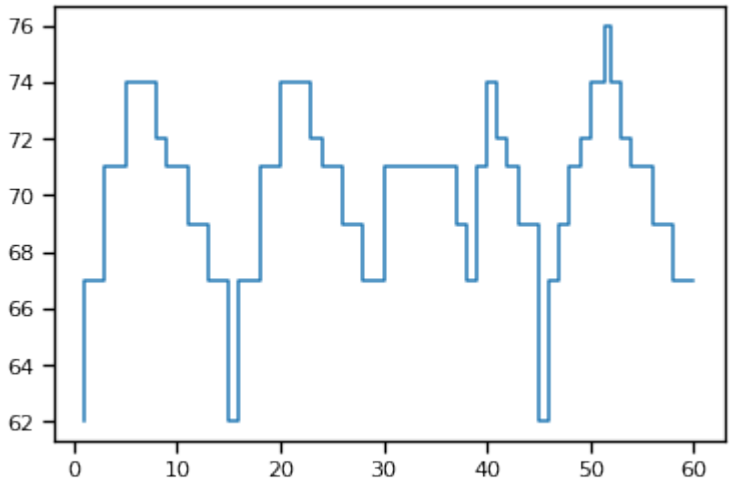
    if standardized:
        x = notelist["Rel. Onset"]
        y = notelist["Rel. MIDI Pitch"]
    else:
        x = notelist["Onset"]
        y = notelist["MIDI Pitch"]

    ax.step(x,y, color=c)

    if mean:
        ax.axhline(y.mean(), color="gray", linestyle="--")

    if sections:
        for l in [ x.max() * i for i in [ 1/4, 1/2, 3/4] ]:
            ax.axvline(l, color="gray", linewidth=1, linestyle="--")
```

[26]:
```
plot_melodic_profile(notelist(german_song))
```

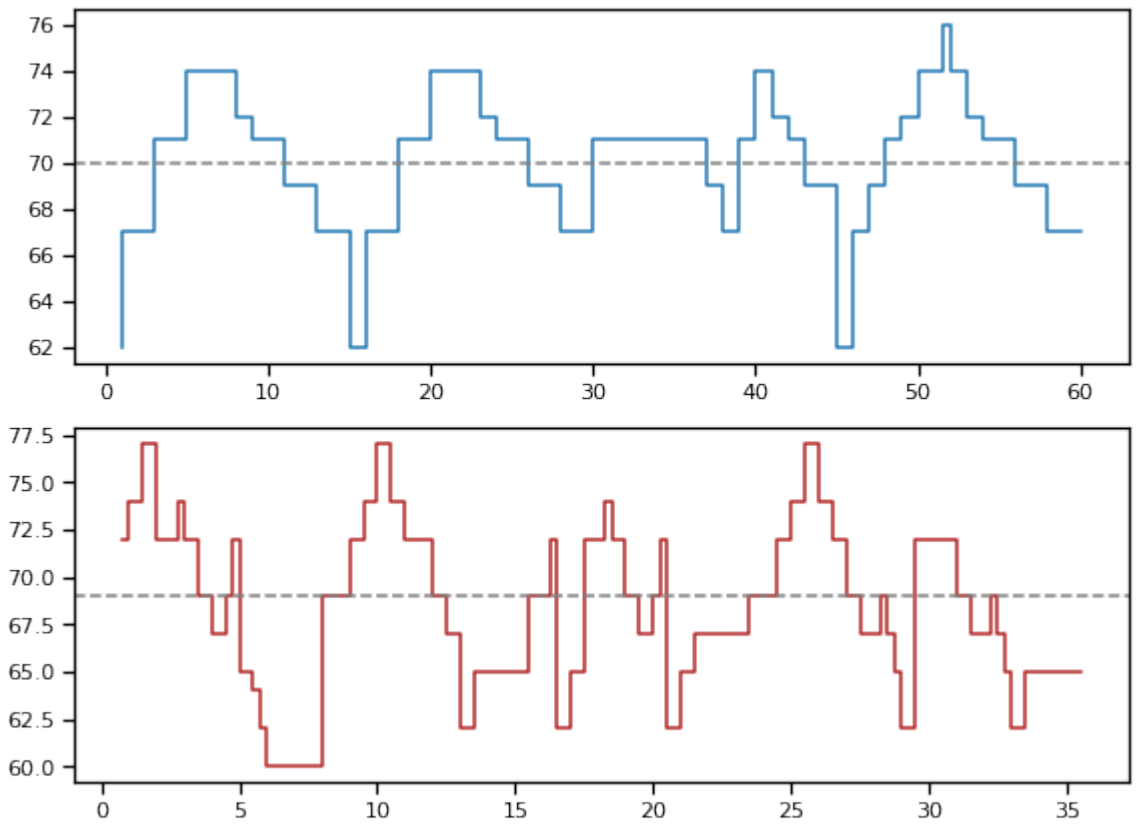


Likewise, we can as easily plot the melodic contour of the Chinese song (we will use a different color).

[27]:
```
fig, axes = plt.subplots(2,1, figsize=(8,6))

plot_melodic_profile(notelist(german_song), ax=axes[0], mean=True)
plot_melodic_profile(notelist(chinese_song), ax=axes[1], c="firebrick", mean=True)

plt.tight_layout()
plt.savefig("img/melodic_profiles.png")
```



The dashed grey lines in both plots show the average MIDI pitch of the song.

But still, it is quite difficult to compare them directly. They differ both with respect to their length (see the numbers on the "Onset" axis) and their pitches (see "MIDI Pitch" axis).

We need to transform them in a way that makes them directly comparable. To that end, we define a new function `standardize()`.

[28]:
```
def standardize(notelist):
    """
    Takes a notelist as input and returns a standardized version.
    """

    notelist["Rel. MIDI Pitch"] = (notelist["MIDI Pitch"] - notelist["MIDI Pitch"].
↪mean()) / notelist["MIDI Pitch"].std()
    notelist["Rel. Duration"] = notelist["Duration"] / notelist["Duration"].sum()
    notelist["Rel. Onset"] = notelist["Onset"] / notelist["Onset"].max()

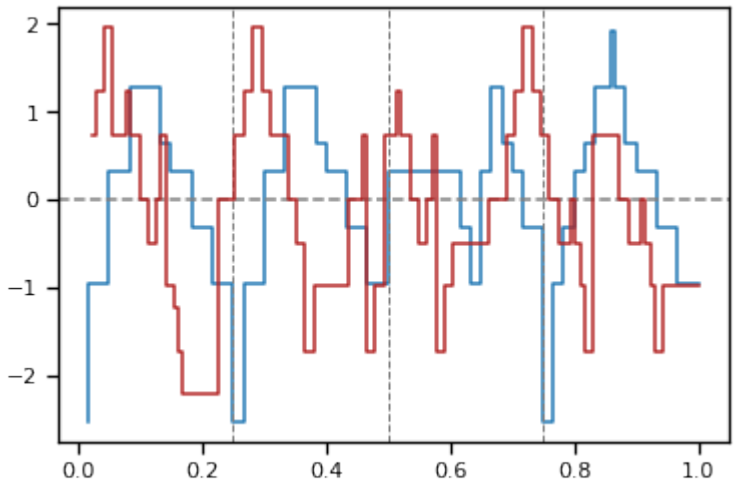
    return notelist
```

[29]:
```
standardize(notelist(german_song))[:8]
```

[29]:

	MIDI Pitch	Duration	Onset	Rel. MIDI Pitch	Rel. Duration	Rel. Onset
0	62	1.0	1.0	-2.543827	0.016667	0.016667
1	67	2.0	3.0	-0.949300	0.033333	0.050000
2	71	2.0	5.0	0.326322	0.033333	0.083333
3	74	3.0	8.0	1.283038	0.050000	0.133333
4	72	1.0	9.0	0.645227	0.016667	0.150000
5	71	2.0	11.0	0.326322	0.033333	0.183333
6	69	2.0	13.0	-0.311489	0.033333	0.216667
7	67	2.0	15.0	-0.949300	0.033333	0.250000

[30]:
```
plot_melodic_profile(standardize(notelist(german_song)), mean=True, sections=True,␣
↪standardized=True)
plot_melodic_profile(standardize(notelist(chinese_song)), c="firebrick",␣
↪standardized=True)
```



Standardizing the songs makes it possible to compare them directly: They have now the same length 1 and their pitches are centered around the mean 0 with a standard deviation of 1.

However, already with two pieces this plot is quite crowded.

[31]:
```
dfs = [ ]

for i, song in enumerate(songs):

```

3.5 Intervals

We have seen that the melodic arc emerges as a stable shape over the entire EFC, and that sub-phrases of the songs likewise have an arc-like shape. In the remainder of this section, we look at **intervals**, the distance between two notes.

Let's come back to the song *Die plappernden Junggesellen*

[36]:
```
german_song.show()
```

We have already extracted its notes and stored them in a DataFrame:

[69]:
```
big_df[ big_df["Song ID"] == 70].head(8)
```

[69]:

	Unnamed: 0	Unnamed: 0.1	MIDI Pitch	Duration	Onset	Rel. MIDI Pitch	Rel. Duration	Rel. Onset	Song ID
2969	2969	2969	62	1.0	1.0	-2.543827	0.016667	0.016667	70
2970	2970	2970	67	2.0	3.0	-0.949300	0.033333	0.050000	70
2971	2971	2971	71	2.0	5.0	0.326322	0.033333	0.083333	70
2972	2972	2972	74	3.0	8.0	1.283038	0.050000	0.133333	70
2973	2973	2973	72	1.0	9.0	0.645227	0.016667	0.150000	70
2974	2974	2974	71	2.0	11.0	0.326322	0.033333	0.183333	70
2975	2975	2975	69	2.0	13.0	-0.311489	0.033333	0.216667	70
2976	2976	2976	67	2.0	15.0	-0.949300	0.033333	0.250000	70

The code above reads as "Select all rows in `big_df` for which the column `Song ID` is equal to 70". The `.head()` method displays the first 5 rows by default but you can specify the number of rows you want to be displayed (here 8).

Focusing on the "MIDI Pitch" column, the notes in the first phrase have MIDI pitch 62, 67, 71, 74, 72. Since intervals correspond to the difference between notes, the intervals for the beginning of this song are:

- +5 (67-62)
- +4 (71-67)

- +3 (74-71)
- -2 (72-74)
- -1 (71-72)
- -2 (69-71)
- -2 (67-69)

The sequence of intervals in this phrase is thus `[+5, +4, +3, -2, -1, -2, -2]`. The signs (+ or -) also reflect the arc-like shape of this first phrase, but the sizes of the intervals are not perfecly balanced. Note that `-2` (two descending semitones, or one descending whole tone) is the most frequent interval.

[38]:
```
all_ints = [ p2 - p1 for i, g in big_df.groupby("Song ID") for p1, p2 in zip(g["MIDI␣
↪Pitch"], g["MIDI Pitch"][1:]) ]
min_int = min(all_ints)
max_int = max(all_ints)
```

[39]:
```
min_int, max_int
```

[39]:
```
(-25, 25)
```

[40]:
```
len(all_ints)
```

[40]:
```
442082
```

[41]:
```
ints_df = pd.DataFrame(0, index=np.arange(min_int,max_int), columns=np.arange(min_int,
↪max_int+1))

for i, g in big_df.groupby("Song ID"):
    intervals = [ p2 - p1 for p1, p2 in zip(g["MIDI Pitch"], g["MIDI Pitch"][1:])]

    for i1, i2 in zip(intervals, intervals[1:]):
        ints_df.loc[i1,i2] += 1
```

[73]:
```
ints_df.loc[-10:10, -10:10]
```

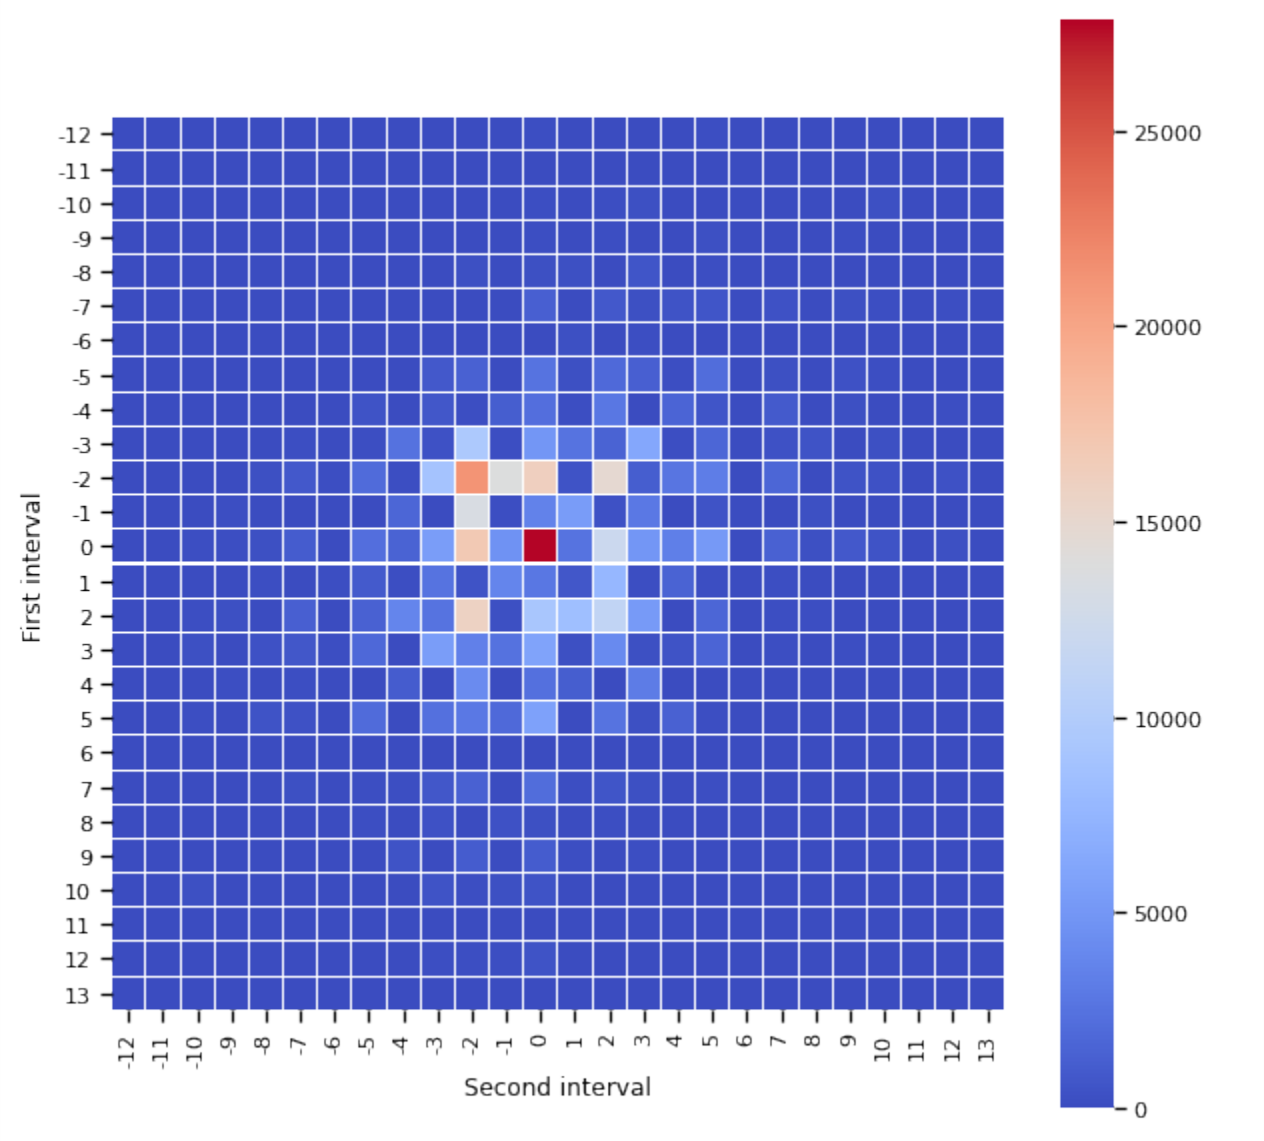
[21 rows x 21 columns]
```

[74]:
```
fig, ax = plt.subplots(figsize=(10,10))
sns.heatmap(ints_df.loc[-12:13,-12:13], cmap="coolwarm", square=True, linewidths=0.01,
↪ax=ax)
plt.ylabel("First interval")
plt.xlabel("Second interval")
plt.show()
```



The two most common interval pairs are `(0,0)` and `(-2,-2)`. A much less frequent pair of intervals is `(5,0)`, but this is still much more frequent than, for example, `(9,9)`.

To which melodic fragments do these correspond?

[44]:
```

CHAPTER

FOUR

SOLOS IN THE *WEIMAR JAZZ DATABASE*

Disclaimer: I am not the expert here!

In this session, we will have a look at is the Jazzomat Research Project that contains the *Weimar Jazz Database* (WJazzD). Let us first browse the site.

One of the outcomes of this research project is the freely-available book:

- Pfleiderer, M., Frieler, K., Abeßer, J., Zaddach, W.-G., & Burkhard, B. (Eds.) (2017). Inside the Jazzomat. New Perspectives for Jazz Research. Mainz: Schott Campus (Open Access).

[1]:
```
import pandas as pd
import numpy as np
import statsmodels.api as sm
import sqlite3

import matplotlib.pyplot as plt
import seaborn as sns
sns.set_style("white")
sns.set_context("talk")
```

The WJazzD can be downloaded at https://jazzomat.hfm-weimar.de/download/download.html A local copy of the database is stored at `data/wjazz.db`. We use the `sqlite3` library to connect to this database.

[2]:
```
conn = sqlite3.connect("data/wjazzd.db")
```

[3]:
```
conn
```

[3]:
```
<sqlite3.Connection at 0x201747b7990>
```

We can now use `pandas` to read the data out of the database.

[4]:
```
solos = pd.read_sql("SELECT * FROM melody", con=conn)
```

The `"SELECT * FROM melody"` means "Select everything from the table 'melody' in the database". Let's look at the first ten entries.

Likewise, we can select the `composition_info` table that contains a lot of metadata for the solos:

[5]:
```
solos_meta = pd.read_sql("SELECT * from solo_info", con=conn)
```

The `.shape` attribute shows us how many solos are in the database.

[6]:
```
solos_meta.shape
```

[6]:
```
(456, 17)
```

The `.sample()` method draws a number of rows at random from a DataFrame.

[13]:
```
solos_meta.sample(5)
```

[13]:
```
     melid  trackid  compid  recordid      performer        title titleaddon  \
429    430      260     236       140  Wayne Shorter   Eighty-One

[5 rows x 26 columns]
```

As we already know, the `.shape` attribute shows the overall size of the table.

[20]:
```
solos.shape
```

[20]:
```
(200809, 26)
```

The `solos` table contains 26 columns that cannot be displayed at once. We can have a look at the column names by using the `.columns` attribute.

[21]:
```
solos.columns
```

[21]:
```
Index(['eventid', 'melid', 'onset', 'pitch', 'duration', 'period', 'division',
       'bar', 'beat', 'tatum', 'subtatum', 'num', 'denom', 'beatprops',
       'beatdur', 'tatumprops', 'f0_mod', 'loud_max', 'loud_med', 'loud_sd',
       'loud_relpos', 'loud_cent', 'loud_s2b', 'f0_range', 'f0_freq_hz',
       'f0_med_dev'],
      dtype='object')
```

A description of what these columns contain is stated on the website: https://jazzomat.hfm-weimar.de/dbformat/dbformat.html

For our analyses it will be usefull to have also the name of the performer in the `solos` DataFrame. We create a **dictionary** that maps the `melid` (unique identification number for each solo) to the name of the performer.

[26]:
```
mapper = dict( solos_meta[["melid", "performer"]].values )
mapper
```

4.2 Pitch vs loudness

Above we have already analyzed some melodic profiles and seen that, on average, the Jazz solos tend not to follow the melodic arch on a global scale. Now, we ask whether the pitch of the notes in the solos are related to another important feature of performance: loudness. The WJazzD contains several measures for loudness (compare the columns in the `solos` DataFrame). Here, we focus on the "Median loudness" which is stored in the `loud_med` column.

Let us look at an example.

[68]:
```
example_solo = solos[ solos["melid"] == 233 ][["pitch", "loud_med"]]
```

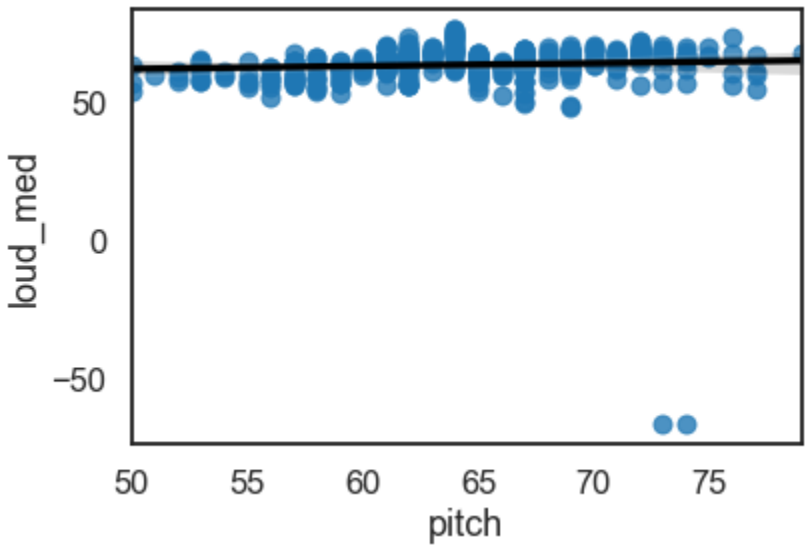
[69]:
```
example_solo
```

[69]:
```
        pitch   loud_med
115075   62.0  67.082700
115076   65.0  65.345677
115077   67.0  66.323539
115078   69.0  69.204257
115079   62.0  69.059581
...       ...        ...
115549   59.0  61.083907
115550   57.0  58.345887
115551   55.0  65.132786
115552   54.0  59.595735
115553   53.0  58.390132

[479 rows x 2 columns]
```

We can get a visual impression of whether there might be a direct relation between the two features by plotting it and drawing a regression line. For this, the `regplot()` function of the `seaborn` library is well-suited.

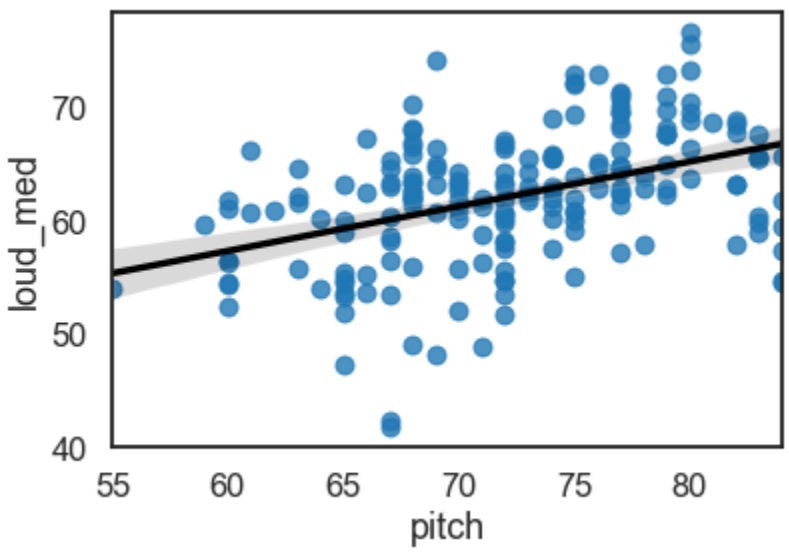
[71]:
```
sns.regplot(data=example_solo, x="pitch", y="loud_med", line_kws={"color":"black"});
```



There seems to be no clear relation; no matter how high the pitch, the loudness stays more or less the same. Let's look at another example!

[73]:
```
example_solo2 = solos[ solos["melid"] == 333 ][["pitch", "loud_med"]]

sns.regplot(data=example_solo2, x="pitch", y="loud_med", line_kws={"color":"black"});
```



In this case, there is a positive trend. The higher the pitch, the louder the performer plays. Since we have now two different examples - in one case no relation, in the other case a positive correlation - we should now look at whether there is a trend emerging from all solos taken together.

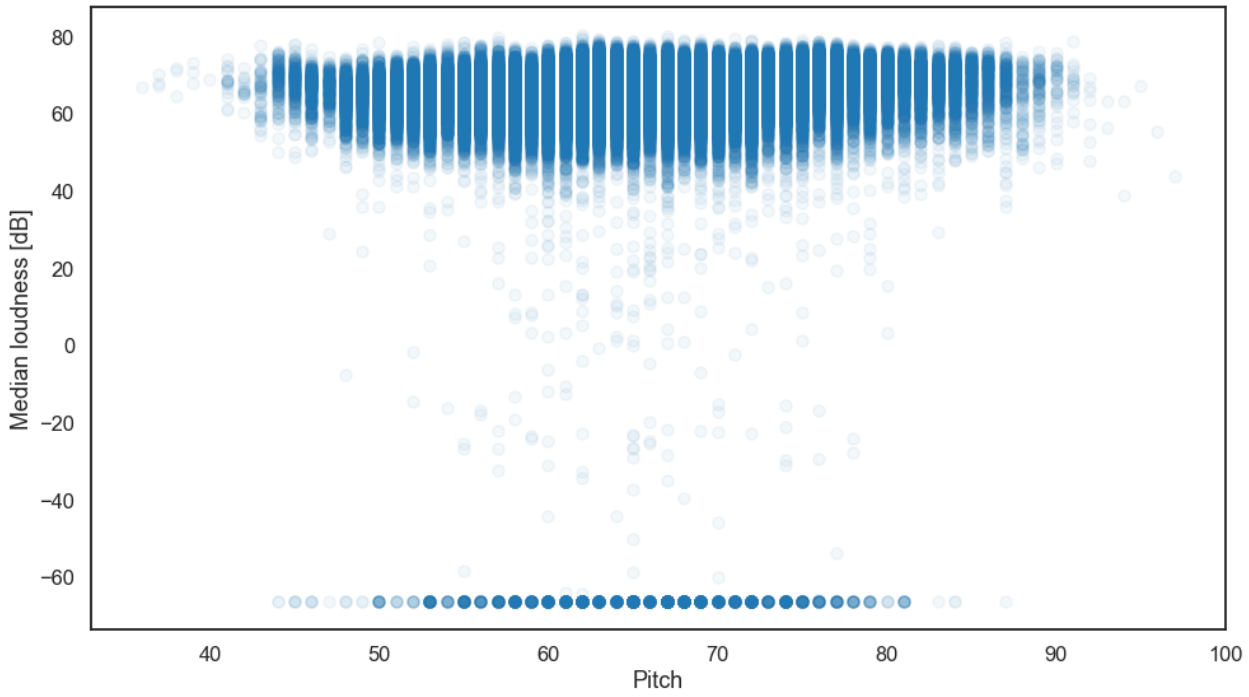
4.3 The "rain cloud" of Jazz solos

We now take all 200'809 notes from all solos and look at the relation between their pitch and their median loudness.

[75]:
```
X = solos[["pitch", "loud_med"]].values
x = X[:,0]
y = X[:,1]

fig, ax = plt.subplots(figsize=(16,9))
ax.scatter(x,y, alpha=0.05)

plt.xlabel("Pitch")
plt.ylabel("Median loudness [dB]")
plt.show()
```



The visual impression is that of a cloud from which rain drops down and forms a puddle. Which trends can we observe?

4.4 Comparing performers

Taking all pieces together was not really informative. Maybe a somewhat closer look brings more to the front. Let us some specific performers whose solos we want to compare.

[76]:
```
selected_performers = ["Charlie Parker", "Miles Davis", "Louis Armstrong", "Herbie␣
↪Hancock", "Von Freeman", "Red Garland"]
```

[78]:
```
grouped_df = solos.groupby("performer")
```

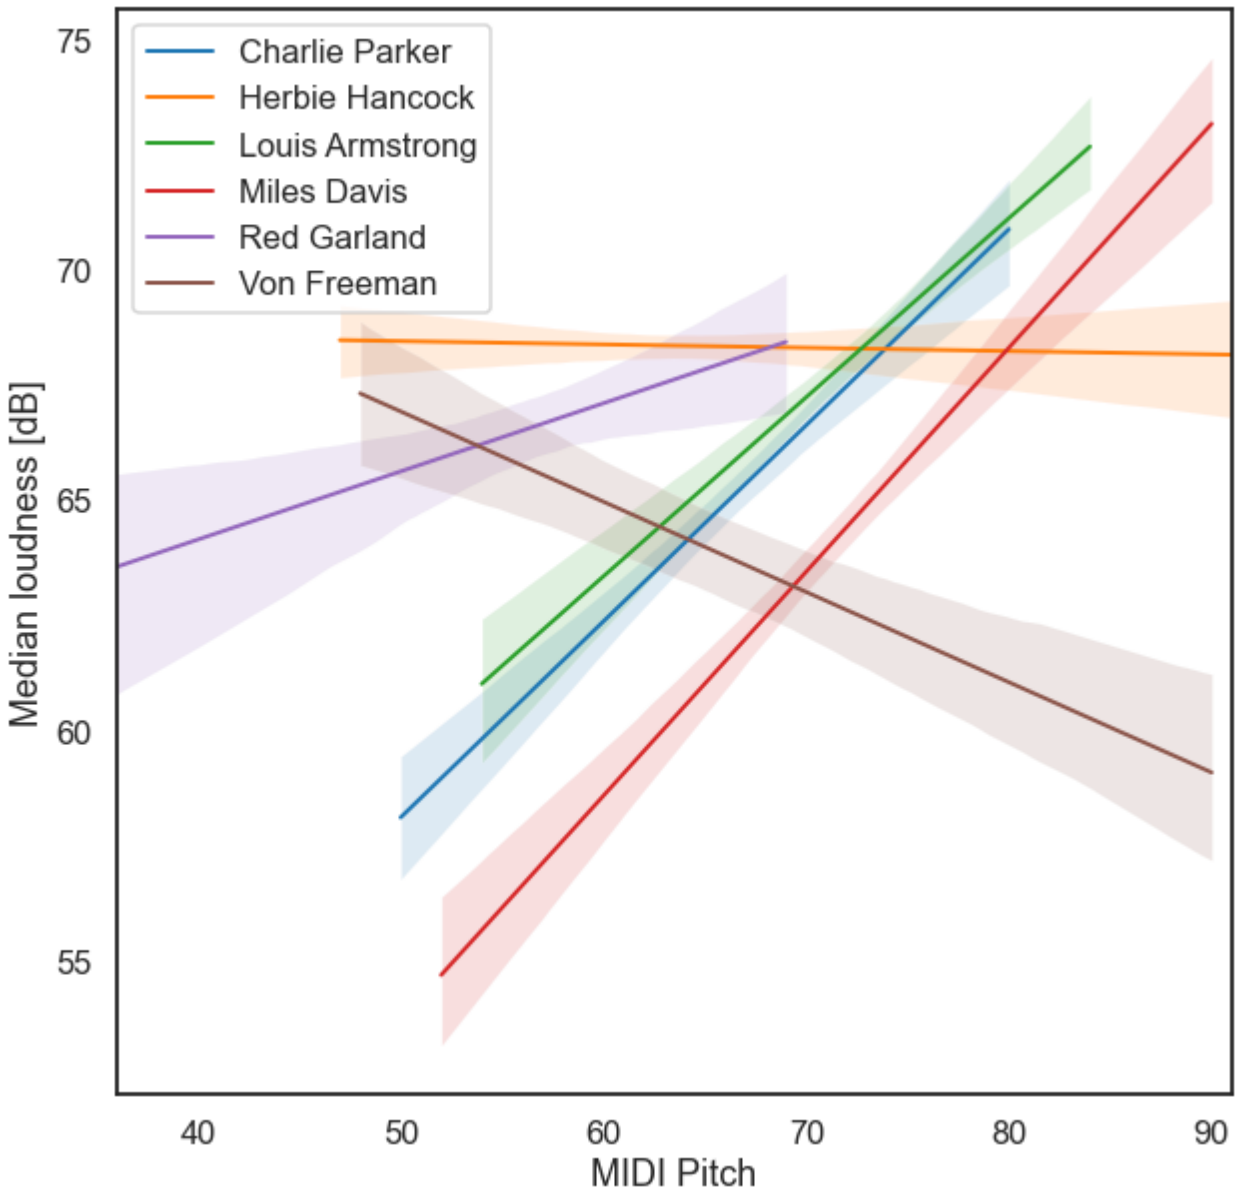
[79]:
```
fig, ax = plt.subplots(figsize=(10,10))

for performer, df in grouped_df:
    if performer in selected_performers:
        sns.regplot(
            data=df,
            x="pitch",
            y="loud_med",
            x_jitter=.1,
            y_jitter=.1,
            scatter_kws={"alpha":.01, "color":"grey"},
            line_kws={"lw":2},
            label=performer,
            scatter=False,
            ax=ax
        )
```

(continues on next page)

(continued from previous page)

```
plt.xlabel("MIDI Pitch")
plt.ylabel("Median loudness [dB]")
plt.legend()
plt.show()
```



Observations:

1. Most performers increase loudness with increasing pitch.
2. Charlie Parker (sax) and Louis Armstrong (t) show very similar patterns but Armstrong is generally higher.
3. Miles Davis (t) is similar to the two but plays generally softer than both.
4. Von Freeman (sax) strongly and Herbie Hancock (p) weakly decrease loudness with increasing pitch (almost all other performers show positive correlations).

5. Red Garland (p) plays generally lower than Herbie Hancock (p) but does show a positive correlation between pitch and loudness (NB: there is only one solo in the database).

Does this tell us something about performer styles or about instruments?

CHAPTER

FIVE

EXERCISE I: THE ANNOTATED BEETHOVEN CORPUS AND THE PANDAS LIBRARY

In the first exercise, you learn how to interact with `pandas` library that is very useful for deadling with tabular data. Moreover, you will have a first look at the data that we work with in the next session, the *Annotated Beethoven Corpus* (ABC). The ABC contains harmonic annotations for all string quartets by Ludwig van Beethoven. The corpus is described in

- Neuwirth, M., Harasim, D., Moss, F. C., & Rohrmeier, M. (2018). The Annotated Beethoven Corpus (ABC): A Dataset of Harmonic Analyses of All Beethoven String Quartets. *Frontiers in Digital Humanities*. https://doi.org/10.3389/fdigh.2018.00016

A study based on this corpus is

- Moss, F. C., Harasim, D., Neuwirth, M., & Rohrmeier, M. (2019). Statistical characteristics of tonal harmony: A corpus study of Beethoven's string quartets. *PLOS ONE*. https://doi.org/10.1371/journal.pone.0217242

Preparation

1. Select one member of your team who shares her/his screen (maybe someone with *some* programming experience).
2. Do all the exercises in that person's notebook together.

If you are not sure how to solve a task, Google is your friend. If you have any questions at any point, don't hesitate to ask me or Sebastian for help.

First, import the `pandas` library in the cell below. It is customary to abbreviate it with `pd`. If you are not sure how to do this, have a look at the "10 minutes to pandas" tutorial or ask Google.

[1]:
```
import pandas as pd
```

You can check which version of `pandas` you are using by using the `.__version__` attribute of `pd`(two underscores on each side).

[ ]:
```

```

The best way to learn how `pandas` works is to use it! The ABC is stored at the following address:

[2]:
```
url = "https://raw.githubusercontent.com/DCMLab/ABC/master/data/all_annotations.tsv"
```

The most important object in `pandas` is a **DataFrame** which is basically just another word for a table.

We can load the ABC from the address that is stored in the variable `url` by passing it to the `.read_table()` method. Assign it to a variable called `abc`. The code for doing this is `abc = pd.read_table(url)`.

[6]:
```
abc = pd.read_csv(url, sep='\t')
```

[7]:
```
abc.tail()
```

[7]:
```
       chord altchord  measure  beat  totbeat timesig  op  no  mov  length  \
28090      I      NaN      171   1.0    542.5     2/2  95  11    4     4.0
28091     V7      NaN      172   1.0    546.5     2/2  95  11    4     4.0
28092      I      NaN      173   1.0    550.5     2/2  95  11    4     4.0
28093      V      NaN      174   1.0    554.5     2/2  95  11    4     4.0
28094  I\\\\      NaN      175   1.0    558.5     2/2  95  11    4     4.0

      global_key local_key pedal numeral form  figbass changes relativeroot  \
28090      false         I   NaN       I  NaN      NaN     NaN          NaN
28091      false         I   NaN       V  NaN      7.0     NaN          NaN
28092      false         I   NaN       I  NaN      NaN     NaN          NaN
28093      false         I   NaN       V  NaN      NaN     NaN          NaN
28094      false         I   NaN       I  NaN      NaN     NaN          NaN

       phraseend
28090      False
28091      False
28092      False
28093      False
28094       True
```

Call the variable `abc` in the next cell.

[ ]:
```

```

As you can see, `pandas` displays the first and the last five rows, and a lot of columns of the table. A very handy way to know how large the table is, is to use the `.shape` attribute of the `abc` DataFrame. It returns a pair `(number_of_rows, number_of_columns)`. Use this attribute in the cell below and compare it to the numbers of rows and columns that are displayed directly below the DataFrame.

[ ]:
```

```

Now, try to figure out what the following columns could mean and write it to the code (like the example for `chord`).

[ ]:
```
column_meanings = """
chord: 'A chord symbol'
measure:
beat:
totbeat:
timesig:
op:
no:
mov:
length:
global_key:
local_key:
numeral:
figbass:
"""
```

We can look at individual columns of the DataFrame by **selecting** them. For example, if we had a DataFrame called `df` with a column named `temperature`, we could look at only this column by writing `df["temperature"]`. In the cell below, select the `chord` column of the DataFrame `abc`.

[ ]:
```

```

Again, we see only the first and last five entries.

We know now how many chords are annotated in this corpus and how we can select individual columns. But how many *different* chords are there? `pandas` has a very useful method for this task, called `.value_counts()`. If you select the `chord` column in the DataFrame `abc` and append the `.value_counts()` method to it, it will show you the number of times each chord appears in the corpus in descending order.

[ ]:

What are the five most common chords? Can you interpret it?

Now, in the big table that we have stored in the variable `abc` there are *all* chords in *all* of Beethoven's string quartets. What if we wanted to look only at a single of these quartets, for example the string quartet no. 11, op. 95 in F minor? The following code shows how we would do it:

```
abc[ abc["op"] == 95 ]
```

This reads as "Show me the `abc` where the `op` column of the `abc` is equal to 95 (note the double ==). In the cell below, show only the rows of the table that belong to the string quartet no. 10, op. 74 in E♭ major.

[ ]:

How could we now count all the chords in op. 74?

[ ]:

How many different chords are in op. 74? (Hint: You don't need to write code for that, the `.value_counts()` method already states it.

Above we have seen that the `global_key` contains the key of the entire piece, while `local_key` contains the keys to which a piece **modulates**. If we wanted to know which chords occur how often *either* in major *or* minor keys, we have to select them explicitly, similarly to how we selected an opus number.

However, the DataFrame does not contain a `mode` column that would contain whether a chord occurs in a major or in a minor segment. But we can work around that! Let us first see, which local keys there are in all string quartets. This can be achieved by first selecting the `local_key` column and then calling the `.unique()` method on it.

[ ]:

Apparently, there is a great variety of keys in Beethoven's string quartes. If we only want to select the major keys, we have to select all keys that start with an uppercase letter, e.g. `'VI'` **or** that start with a flat (♭, here represented by the letter `b`) **and** have uppercase letters following, for example `'bIV'`. This is a quite complicated condition. For tasks like this, one can use so-called **regular expressions** (not necessary to know exactly what this means yet). The condition mentioned above would be expressed as follows:

[ ]:
```
major_condition = "^b?[A-Z]"
```

The `^b?` part means "has the letter 'b' at the beginning but only once", and the `[A-Z]` part means "any uppercase letter". Consequently, we can select all pieces in the major mode by

[ ]:
```
abc[ abc["local_key"].str.match(major_condition) ]
```

Take the above expression and count the chords in all major keys in the cell below.

[ ]:

How would we have to change `major_condition` so that it selects only minor keys? Save the condition for minor keys in a variable `minor_condition` in the cell below.

[ ]:

Now, we are in the position to select all minor-key segments from the string quartets and count the chords!

[ ]:

Compare the first couple of chords in major and minor. Can you interpret it?

Congratulations! You completely solved the first exercise!

CHAPTER

SIX

RENAISSANCE CADENCES

This part of the course was taught by Prof. Richard Freedman, Haverford College who introduced the Lost Voices project and in particular how one can use this corpus for both close and distant reading analyses. Richard's sides can be accessed here.

CHAPTER

SEVEN

EXERCISE II: LOST VOICES CADENCE DATA

Notebook by Richard Freedman (adapted by Fabian Moss)

see https://digitalduchemin.org

As always, we start by importing a number of libraries that contain certain functions which we will use later in the analyses.

[19]:
```
import pandas as pd # working with tabular data
import altair as alt # visualization library; see https://altair-viz.github.io/
alt.renderers.enable('altair_viewer', inline=True) # to display the charts inline
import altair_viewer as av
from pathlib import Path # to handle files
import requests # to communicate with web servers
```

7.1 Get the Cadence Metadata from github as DataFrame

The cadence data from the Digital DuChemin project are available on GitHub. Conveniently, the cadence data is already stored in a CSV file that we can download and store in a table. The function below encapsulates these steps so that when we call it, it returns a dataframe with the stored cadence data.

[20]:
```
# get the data function
def get_data():
    url = "https://raw.githubusercontent.com/RichardFreedman/LostVoicesCadenceViewer/
↪main/LV_CadenceData.csv"
    cadence_data_raw = pd.read_csv(url)
    # The following adds the list of 'similar' cadences to the DF
    cadence_json =  requests.get("https://raw.githubusercontent.com/bmill42/DuChemin/
↪master/phase1/data/duchemin.similarities.json").json()
    cadence_data_raw['similarity'] = cadence_json
    return  cadence_data_raw

cadence_data_raw = get_data()
```

The variable `cadence_data_raw` now contains the cadence data. Remember that we can use the `.head()` method to desplay the first couple of rows. Display the first 10 rows in the next cell.

[21]:
```
cadence_data_raw.head(10)
```

[21]:
```

```

Do you understand what kind of information each column contains? Interpret the contents of the following columns:

- `final_cadence`
- `cadence_final_tone`
- `cadence_role_cantz` / `cadence_role_tenz`
- `cadence_kind` / `cadence_kind_before` / `cadence_kind_after`
- `similarity` (looking back at the definition of the `get_data` function might help)

7.1.1 Get "Counts" for Values of a Particular Column

Use the `value_counts()` method to count the occurrences in the `cadence_kind` column of the DataFrame. Remember that you can select a column of a DataFrame like this: `df[col_name]` where `df` is the name of the variable that stores the DataFrame and `col_name` is the name of the column. Which cadence types are most frequent in this repertoire? Do you understand each cadence type?

[22]:
```
cadence_data_raw['cadence_kind'].value_counts()
```

[22]:
```
Authentic    882
Plagal       158
Phrygian      98
CadInCad      37
CAD NDLT      20
Name: cadence_kind, dtype: int64
```

7.1.2 Sort Data According to Selected Columns

Use the `.sort_values()` method to sort the raw cadence data by the final tone of the cadence **and** by the candence kind. Remember that this method takes either a column name or a list of column names as input.

The `.sort_values()` method is documented here: https://pandas.pydata.org/pandas-docs/stable/reference/api/pandas.DataFrame.sort_values.html As described there, you can reverse the ascending order (default) of the sorted values by changing a keyword to the method. Store the result in a variable named `Sorted` (uppercase S!) and inspect its first 5 rows.

[23]:
```
Sorted = cadence_data_raw.sort_values(['cadence_final_tone','cadence_kind'],␣
↪ascending=False)
Sorted.head(5)
```

[23]:
```
                                        phrase_number  \
703            DC0511.3: Et vous tuez le corps et l'ame
1109      DC0114.9: Elle me paist ceste seconde Heleine
```

66                    NaN                  G              None       Plagal

     cadence_final_tone_before cadence_final_tone_after cadence_kind_before  \
703                          D                        D           Authentic
1109                         C                        A           Authentic
7                            C                        C           Authentic
16                           G                        G           Authentic
66                     B-flat                         G           Authentic

     cadence_kind_after final_cadence           similarity
703            Phrygian             G                   []
1109          Authentic             A                   []
7             Authentic             G                [373]
16            Authentic             G  [66, 132, 335, 512]
66            Authentic             G                 [16]
```

`Sorted` now contains the phrases sorted according to the tone of the final cadence and the kind of the cadence. As you can see, there are a lot of repeating values adjacent to each other.

A better overview is obtained by **grouping** the data with the `.groupby()` method. Like `.value_counts()` this method takes a column name or a list of column names as input.

7.2 Grouping

Group the data by the same two columns as before and store the result in a variable `grouped`.

[24]:
```
grouped = cadence_data_raw.groupby(['cadence_final_tone', 'final_cadence'])
```

What happens if you want to inspect the grouped data?

[25]:
```
grouped
```

[25]:
```
<pandas.core.groupby.generic.DataFrameGroupBy object at 0x00000225571E6C10>
```

Most likely, you didn't see anything. That is because you didn't yet specify in which way the grouped data should be displayed. Here, we would like to count the cadences. Thus, we apply the `.count()` method to the grouped data.

[26]:
```
grouped.count()
```

[26]:

-

7.2.1 Visualizations

In the following, you see a number of visualizations of the cadence data. For each of these figures, write down what it shows and interpret what you see (e.g. the most interesting observation).

7.3 Synoptic View of Cadence Types, Tones, and Last Cadence of Piece

[39]:
```
#Now the generic views and full data sets

all_tone_1 = alt.Chart(cadence_data_raw).mark_circle().encode(
    x='cadence_final_tone',
    y='final_cadence',
    color='cadence_kind'
).properties(
    width=400,
    title='All Cadence Tones, Types, and Finals'
)

all_tone_1.save('img/chart.html', embed_options={'renderer':'svg'})
all_tone_1
```

CHAPTER

EIGHT

DATA-DRIVEN MUSIC HISTORY

[1]:
```
import pandas as pd # for working with tabular data
pd.set_option('display.max_columns', 500)
import matplotlib.pyplot as plt # for plotting
plt.style.use("fivethirtyeight") # select specific plotting style
import seaborn as sns; sns.set_context("talk")
import numpy as np
```

8.1 Research Questions

- General: How can we study historical changes quantitatively?
- Specific: What can we say about the history of tonality based on a dataset of musical pieces?

8.2 A bit of theory

[2]:
```
note_names = list("FCGDAEB") # diatonic note names in fifths ordering
note_names
```

[2]:
```
['F', 'C', 'G', 'D', 'A', 'E', 'B']
```

[3]:
```
accidentals = ["bb", "b", "", "#", "##"] # up to two accidentals is suffient here
accidentals
```

[3]:
```
['bb', 'b', '', '#', '##']
```

[4]:
```
lof = [ n + a for a in accidentals for n in note_names ] # lof = "Line of Fifths"
print(lof)
```

```
['Fbb', 'Cbb', 'Gbb', 'Dbb', 'Abb', 'Ebb', 'Bbb', 'Fb', 'Cb', 'Gb', 'Db', 'Ab', 'Eb',
↪'Bb', 'F', 'C', 'G', 'D', 'A', 'E', 'B', 'F#', 'C#', 'G#', 'D#', 'A#', 'E#', 'B#',
↪'F##', 'C##', 'G##', 'D##', 'A##', 'E##', 'B##']
```

[5]:
```
len(lof) # how long is this line-of-fifths segment?
```

[5]:
```
35
```

We call the elements on the line of fifths **tonal pitch-classes**

8.3 Data

8.3.1 A (kind of) large corpus: TP3C

Here, we use a dataset that was specifically compiled for this kind of analysis, the Tonal pitch-class counts corpus (TP3C) (Moss, Neuwirth, Rohrmeier, 2020)

- 2,012 pieces
- 75 composers
- approx. spans 600 years of music history
- does not contain complete pieces but only counts of tonal pitch-classes

[6]:
```
import pandas as pd # to work with tabular data

url = "https://raw.githubusercontent.com/DCMLab/TP3C/master/tp3c.tsv"
data = pd.read_table(url)

data.sample(10)
```

```

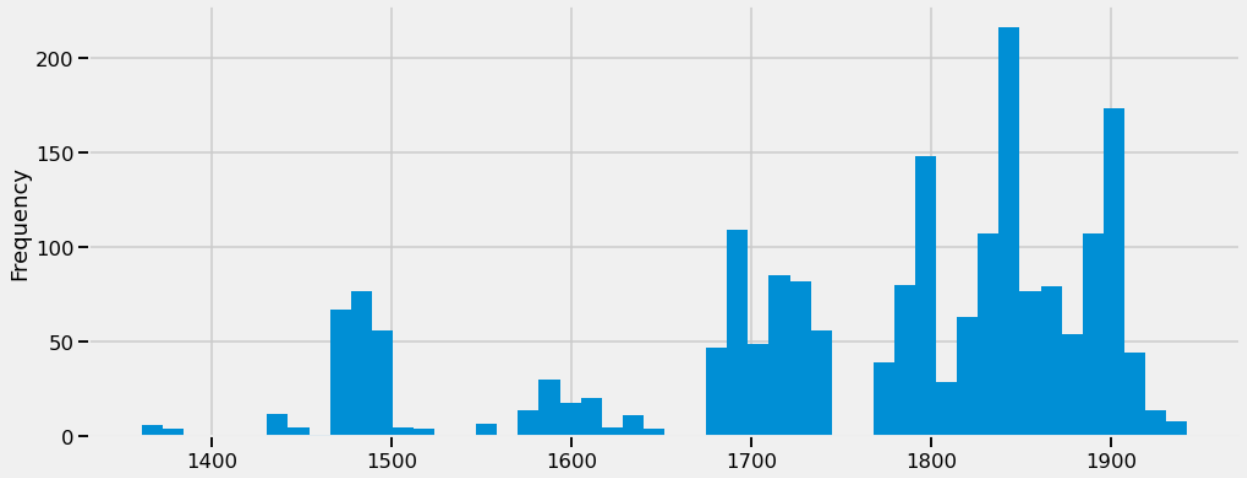
[8]:
```
data["display_year"].plot(kind="hist", bins=50, figsize=(15,6)); # historical overview
```



- it can be seen that there are large gaps and that some historical periods are underrepresented
- however, it is not so obvious how to fix that
- do we want a uniform distribution over time?
- do we want a “historically accurate” distribution?
- do we want to remove geographical/gender/class/instrument/etc. biases?
- on one hand, balanced datasets are likely not to reflect historical realities
- on the other hand, such datasets rather represent the “canon”, that is a contemporary selection of “valuable” compositions that may differ greatly from what was considered relevant at the time

–> There is no unique objective answer to these questions. It is important to be aware of these limitations and take

them into account when interpreting the results

For this workshop we ignore all the metadata about the pieces (titles, composer names etc.) but only focus on their tonal material. Therefore, we don't need all the columns of the table.

[9]:
```
tpc_counts = data.loc[:, lof] # select all rows (":") and the lof columns
tpc_counts.sample(20)
```

```

[11]:
```
piece = tpc_counts.iloc[10]

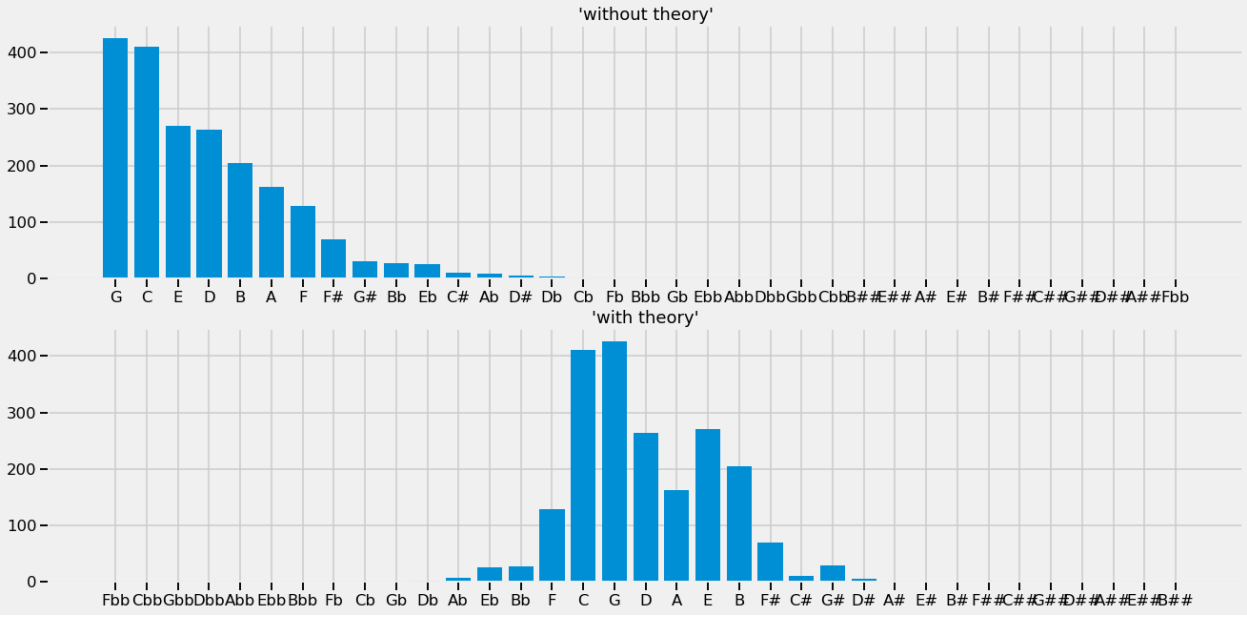
fig, axes = plt.subplots(2, 1, figsize=(20,10))

axes[0].bar(piece.sort_values(ascending=False).index, piece.sort_
↪values(ascending=False))
axes[0].set_title("'without theory'")

axes[1].bar(piece.index, piece)
axes[1].set_title("'with theory'")

# plt.savefig("img/random_piece.png")
# plt.show()
```

[11]:
```
Text(0.5, 1.0, "'with theory'")
```



Let us have an overview of the note counts in these pieces!

If we would just look at the raw counts of the tonal pitch-classe, we could not learn much from it. Using a theoretical model (the line of fifths) shows that the notes in pieces are usually come from few adjacent keys (you don't say!).

We probably have very long pieces (sonatas) and very short pieces (songs) in the dataset. Since we don't want length (or the absolute number of notes in a piece) to have an effect, we rather consider tonal pitch-class distributions instead counts, by normalizing all pieces to sum to one.

[12]:
```
tpc_dists = tpc_counts.div(tpc_counts.sum(axis=1), axis=0)
tpc_dists.sample(20)
```

```

(continues on next page)

(continued from previous page)

```
80    0.0  0.0  0.0  0.0  0.0
```

For further numerical analysis, we extract the data from this table and assign it to a variable `X`.

[14]:
```
# extract values of table to matrix
X = tpc_dists.values

X.shape # shows (#rows, #columns) of X
```

[14]:
```
(2012, 35)
```

Now, `X` is a 2012 × 35 matrix where the rows represent the pieces and the columns (also called "features" or "dimensions") represent the relative frequency of tonal pitch-classes.

Thinking in 35 dimensions is quite difficult for most people. Without trying to imagine what this would look like, what can we already say about this data?

Since each piece is a point in this 35-D space and pieces are represented as vectors, pieces that have similar tonal pitch-class distributions must be close in this space (whatever this looks like).

What groups of pieces that cluster together? Maybe pieces of the same composer are similar to each other? Maybe pieces from a similar time? Maybe pieces for the same instruments?

If we find clusters, these would still be in 35-D and thus difficult to interpret. Luckily, there are a range of so-called *dimensionality reduction* methods that transform the data into lower-dimensional spaces so that we actually can look at them.

A very common dimensionality reduction method is **Principal Components Analysis (PCA)**.

The basic idea of PCA is:

- find dimensions in the data that maximize the variance in this direction
- these dimensions have to be orthogonal to each other (mutually independent)
- these dimensions are called the *principal components*
- each principal component is associated with how much of the data variance it explains

[15]:
```
import numpy as np # for numerical computations
import sklearn
from sklearn.decomposition import PCA # for dimensionality reduction

pca = sklearn.decomposition.PCA(n_components=35) # initialize PCA with 35 dimensions
pca.fit(X) # apply it to the data
variance = pca.explained_variance_ratio_ # assign explained variance to variable
```

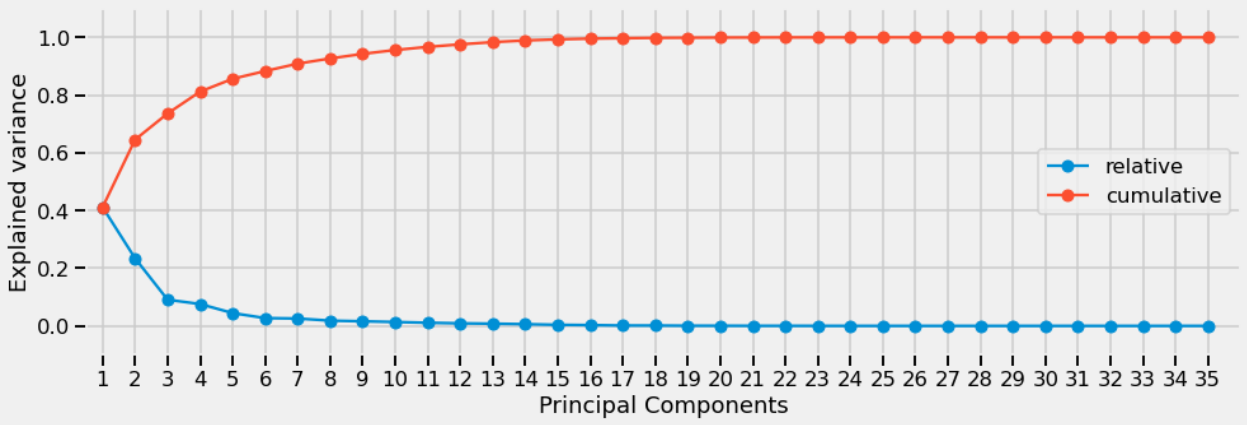
[16]:
```
fig, ax = plt.subplots(figsize=(14,5))
x = np.arange(35)
ax.plot(x, variance, label="relative", marker="o")
ax.plot(x, variance.cumsum(), label="cumulative", marker="o")
ax.set_xlim(-0.5, 35)
ax.set_ylim(-0.1, 1.1)
ax.set_xlabel("Principal Components")
ax.set_ylabel("Explained variance")
plt.xticks(np.arange(len(lof)), np.arange(len(lof)) + 1) # because Pyhon starts␣
↪counting at 0

plt.legend(loc="center right")
plt.tight_layout()
```

(continues on next page)

(continued from previous page)

```
# plt.savefig("img/explained_variance.png")
# plt.show()
```



[17]:
```
variance[:5]
```

[17]:
```
array([0.41144591, 0.23410347, 0.09063507, 0.07574242, 0.04436989])
```

The first principal component explains 41.1% of the variance of the data, the second explains 23.4% and the third 9%. Together, this amounts to 73.6%.

Almost three quarters of the variance in the dataset is retained by reducing the dimensionality from 35 to 3 dimensions (8.6%)! If we reduce the data to two dimensions, we still can explain ≈ 65% of the variance.

This is great because it means that we can look at the data in 2 or 3 dimensions without loosing too much information.

8.4 Recovering the line of fifths from data

[18]:
```
pca3d = PCA(n_components=3)
pca3d.fit(X)

X_ = pca3d.transform(X)
X_.shape
```

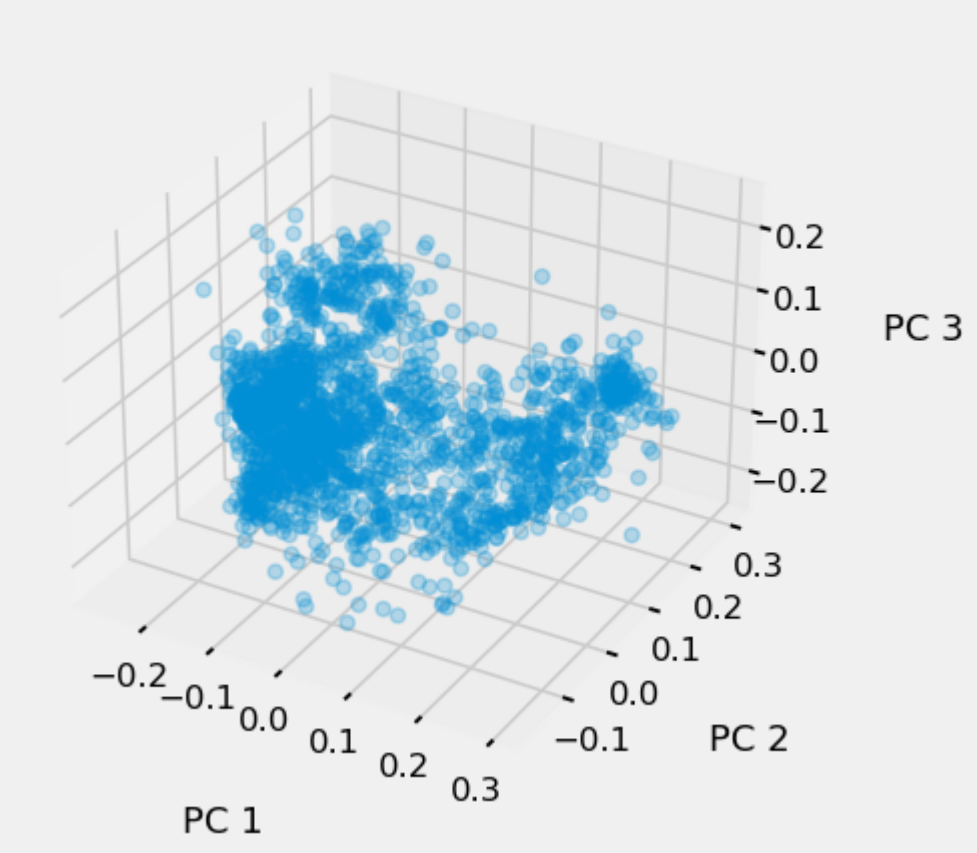
[18]:
```
(2012, 3)
```

[20]:
```
from mpl_toolkits.mplot3d import Axes3D

fig = plt.figure(figsize=(6,6))

ax = fig.add_subplot(111, projection='3d')
ax.scatter(X_[:,0], X_[:,1], X_[:,2], s=50, alpha=.25) # c=cs,
ax.set_xlabel("PC 1", labelpad=30)
ax.set_ylabel("PC 2", labelpad=30)
ax.set_zlabel("PC 3", labelpad=30)

plt.tight_layout()
# plt.savefig("img/3d_scatter.png")
# plt.show()
```



Each piece in this plot is represented by a point in 3-D space. But remember that this location represents ~75% of the information contained in the full tonal pitch-class distribution. In 35-D space each dimension corresponded to the relative frequency of a tonal pitch-class in a piece.

- What do these three dimensions signify?
- How can we interpret them?

Fortunately, we can inspect them individually and try to interpret what we see.

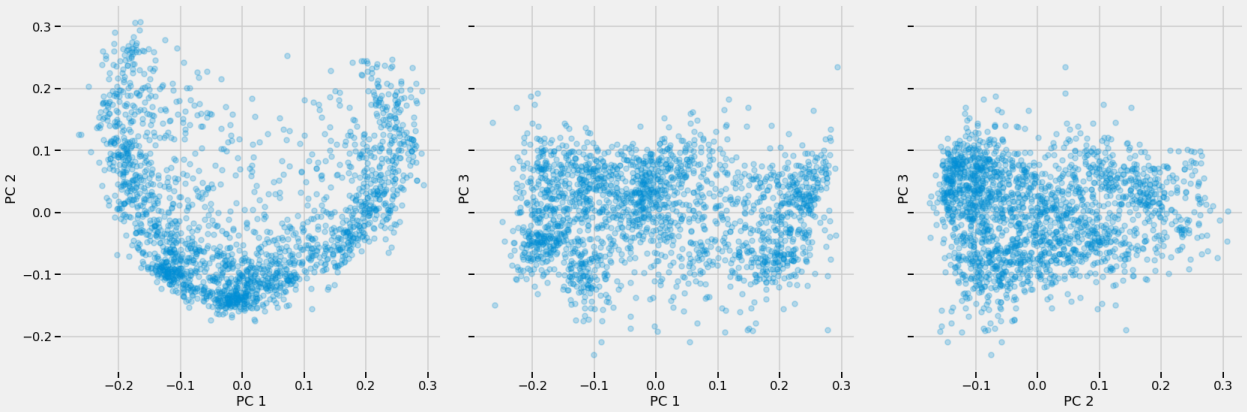
[21]:
```
from itertools import combinations

fig, axes = plt.subplots(1,3, sharey=True, figsize=(24,8))

for k, (i, j) in enumerate(combinations(range(3), 2)):

    axes[k].scatter(X_[:,i], X_[:,j], s=50, alpha=.25, edgecolor=None)
    axes[k].set_xlabel(f"PC {i+1}")
    axes[k].set_ylabel(f"PC {j+1}")
    axes[k].set_aspect("equal")

plt.tight_layout()
# plt.savefig("img/3d_dimension_pairs.png")
# plt.show()
```



Clearly, looking at two principal components at a time shows that there is some latent structure in the data. How can we understand it better?

One way to see whether the pieces are clustered together systematically be coloring them according to some criterion.

As always, many different options are available. For the present purpose we will use the most simple summary of the piece: its most frequent note (which is the *mode* of its pitch-class distribution in statistical terms) and call this note its **tonal center**.

This will also allow to map the tonal pitch-classes on the line of fifths to colors.

[22]:
```
tpc_dists["tonal_center"] = tpc_dists.apply(lambda piece: np.argmax(piece[lof].
↪values) - 15, axis=1)
tpc_dists.sample(10)
```

```

8.5 Historical development of tonality

The line of fifths is an important underlying structure for pitch-class distributions in tonal compositions

But we have treated all pieces in our dataset as synchronic and have not yet taken their historical location into account.

Let's assume the pitch-class content of a piece spreads on the line of fifths from F to A♯. This means, its range on the line of fifths is $10 - (-1) = 11$. The piece covers eleven consecutive fifths on the lof.

We can generalize this calculation and write a function that calculates the range for each piece in the dataset.

[25]:
```
def lof_range(piece):
    l = [i for i, v in enumerate(piece) if v!=0]
    return max(l) - min(l)
```

[26]:
```
data["lof_range"] = data.loc[:, lof].apply(lof_range, axis=1) # create a new column
data.sample(20)
```

528      0         22
1765     0         11
1300     0          9
204      0         19
1858     0         19
468      0         10
439      0         11
441      0         14
```

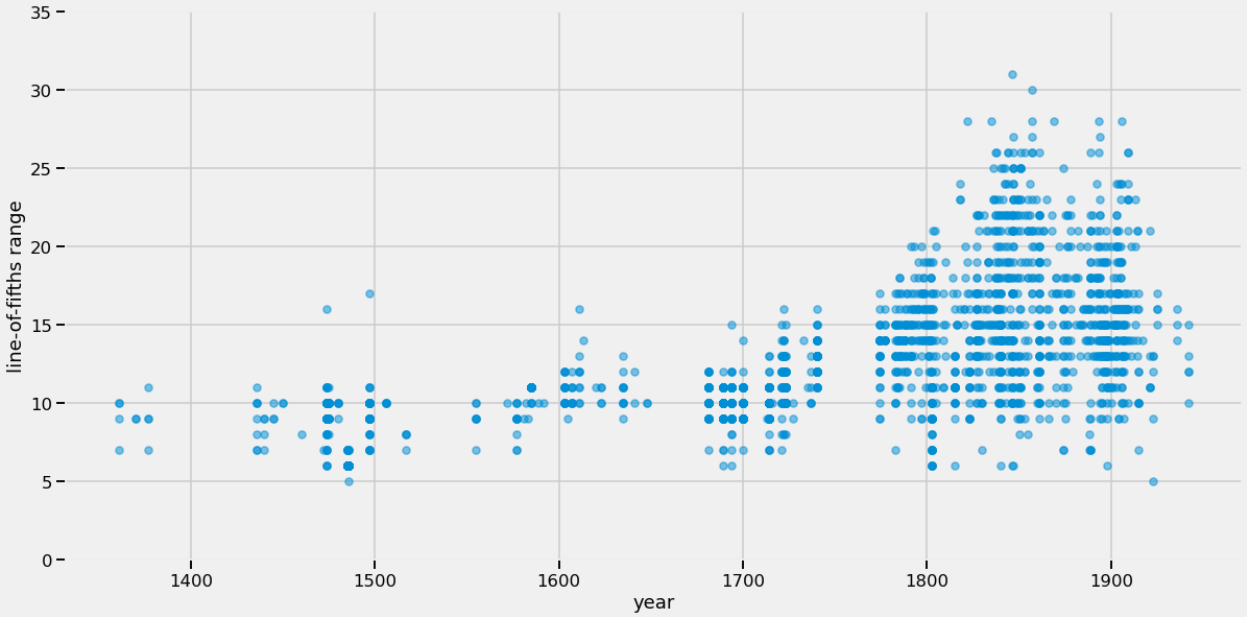
This allows us now to take the `display_year` (composition or publication) and `lof_range` (range on the line of fifths) features to observe historical changes.

[30]:
```
fig, ax = plt.subplots(figsize=(18,9))
```

(continues on next page)

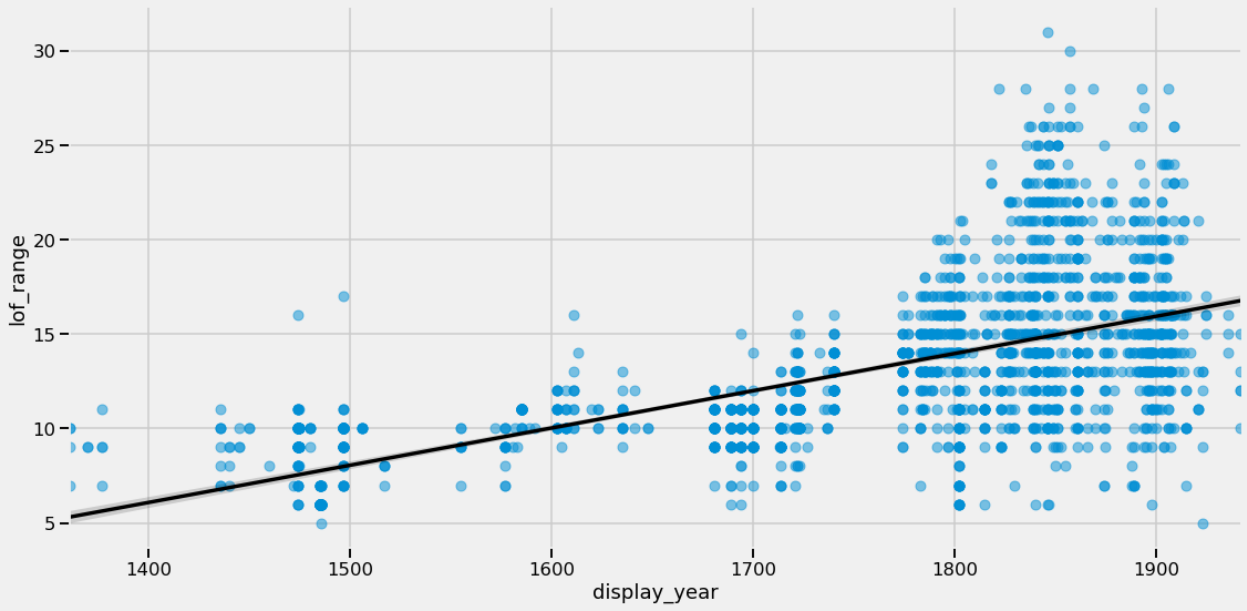
(continued from previous page)

```
ax.scatter(data["display_year"].values, data["lof_range"].values, alpha=.5, s=50)
ax.set_ylim(0,35)
ax.set_xlabel("year")
ax.set_ylabel("line-of-fifths range");
# plt.savefig("img/hist_scatter.png");
```



We could try to fit a line to this data to see whether there is a trend (kinda obvious here).

[32]:
```
g = sns.lmplot(
    data=data,
    x="display_year",
    y="lof_range",
    line_kws={"color":"k"},
    scatter_kws={"alpha":.5},
#     lowess=True,
    height=8,
    aspect=2
);
# g.savefig("img/hist_scatter_line.png");
```



But actually, this is not the best idea. Why should any historical process be linear? More complex models might make more sense.

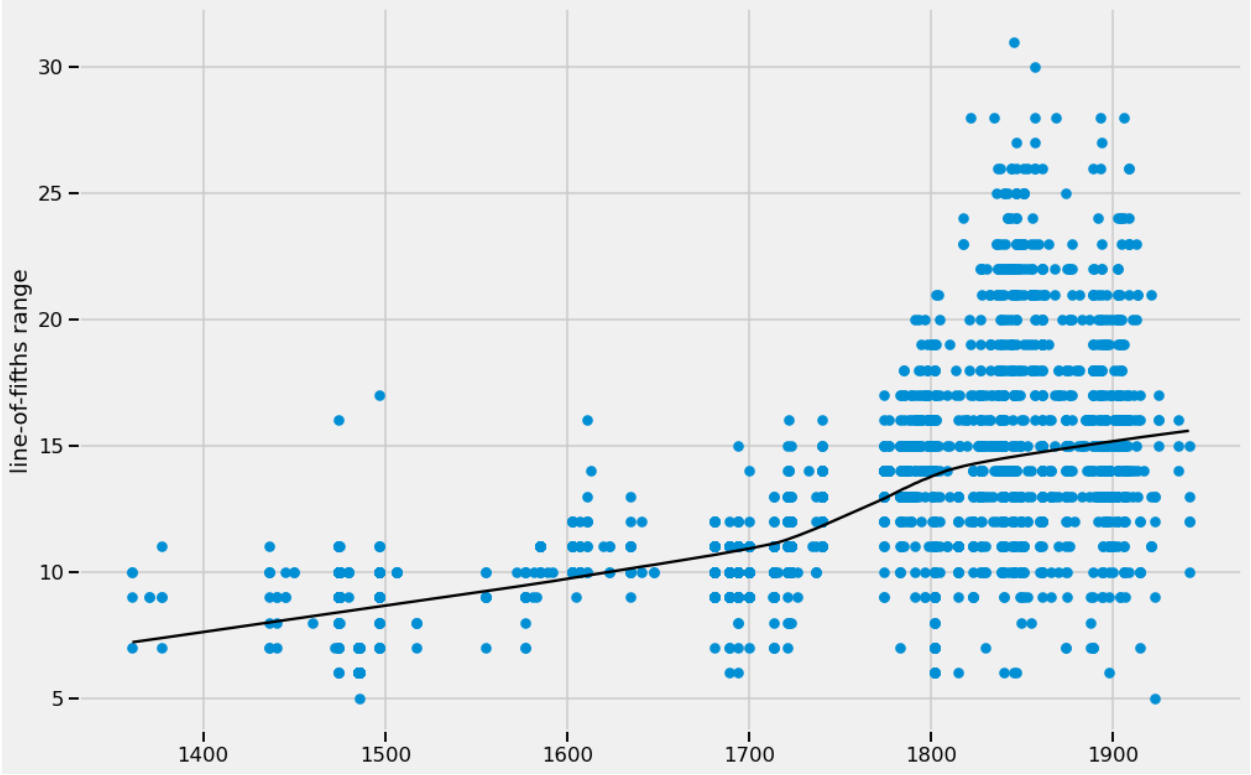
A more versatile technique is *Locally Weighted Scatterplot Smoothing* (LOWESS) that locally fits a polynomial. Using this method, we see that a non-linear process is displayed.

[34]:
```
from statsmodels.nonparametric.smoothers_lowess import lowess

x = data.display_year
y = data.lof_range
l = lowess(y,x)

fig, ax = plt.subplots(figsize=(15,10))

ax.scatter(x,y, s=50)
ax.plot(l[:,0], l[:,1], c="k")
ax.set_ylabel("line-of-fifths range");
# plt.savefig("img/hist_scatter_lowess.png")
# plt.show()
```



8.6 If there is time: some more advanced stuff

[35]:
```
B = 200
delta = 1/10

fig, ax = plt.subplots(figsize=(16,9))

x = data.display_year
y = data.lof_range
l = lowess(y,x, frac=delta)

ax.scatter(x,y, s=50, alpha=.25)

for _ in range(B):
    resampled = data.sample(data.shape[0], replace=True)

    xx = resampled.display_year
    yy = resampled.lof_range
    ll = lowess(yy,xx, frac=delta)

    ax.plot(ll[:,0], ll[:,1], c="k", alpha=.05)

ax.plot(l[:,0], l[:,1], c="yellow")

## REGIONS
from matplotlib.patches import Rectangle
```

(continues on next page)

(continued from previous page)

```
text_kws = {
    "rotation" : 90,
    "fontsize" : 16,
    "bbox" : dict(
        facecolor="white",
        boxstyle="round"
    ),
    "horizontalalignment" : "center",
    "verticalalignment" : "center"
}

rect_props = {
    "width" : 40,
    "zorder" : -1,
    "alpha" : 1.
}

stylecolors = plt.rcParams["axes.prop_cycle"].by_key()["color"]

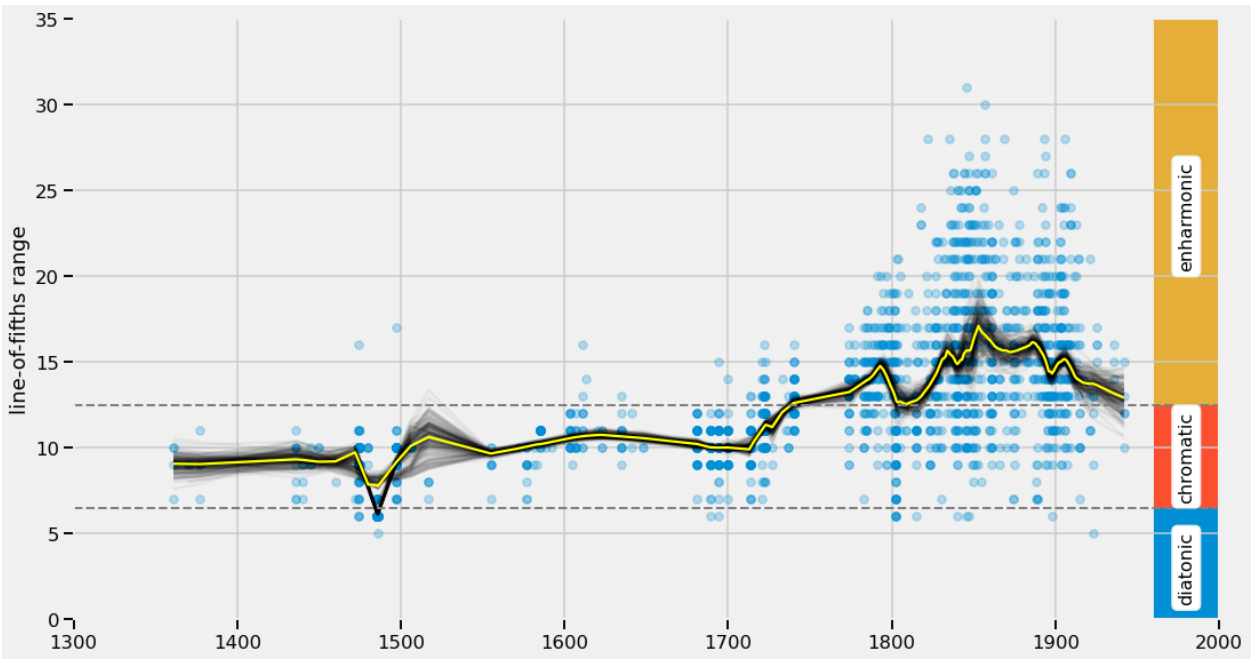
ax.text(1980, 3, "diatonic", **text_kws)
ax.axhline(6.5, c="gray", linestyle="--", lw=2) # dia / chrom.
ax.add_patch(Rectangle((1960,0), height=6.5, facecolor=stylecolors[0], **rect_props))

ax.text(1980, 9.5, "chromatic", **text_kws)
ax.axhline(12.5, c="gray", linestyle="--", lw=2) # chr. / enh.
ax.add_patch(Rectangle((1960,6.5), height=6, facecolor=stylecolors[1], **rect_props))

ax.text(1980, 23.5, "enharmonic", **text_kws)
ax.add_patch(Rectangle((1960,12.5), height=28, facecolor=stylecolors[2], **rect_
↪props))

ax.set_ylim(0,35)
ax.set_xlim(1300,2000)

ax.set_ylabel("line-of-fifths range");
# plt.savefig("img/final.png", dpi=300)
# plt.show()
```



Usung bootstrap sampling we achieve an estimation of the local varience of the data and thus of the diversity in the note usage of the musical pieces.

We also can distinguish three regions in terms of line-of-fifth range: diatonic, chromatic, and enharmonic.

Grouping the data together in these three regions, we see a clear change from diatonic and chromatic to chromatic and enharmonic pieces over the course of history.

[36]:
```
epochs = {
    "Renaissance" : [1300, 1549],
    "Baroque" : [1550, 1649],
    "Classical" : [1650, 1749],
    "Early\nRomantic" : [1750, 1819],
    "Late Romantic/\nModern" : [1820, 2000]
}

strata = [
    "diatonic",
    "chromatic",
    "enharmonic"
]

widths = data[["display_year", "lof_range"]].sort_values(by="display_year").reset_
↪index(drop=True)

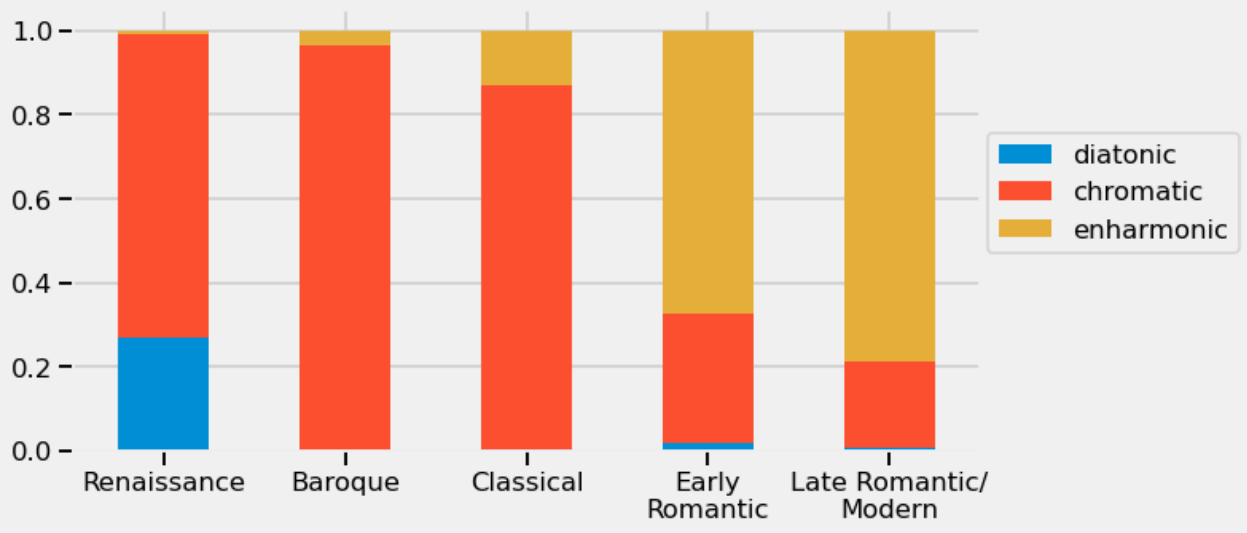
df = pd.concat(
    [
        widths[
            (widths.display_year >= epochs[e][0]) & (widths.display_year <=␣
↪epochs[e][1])
        ]["lof_range"].value_counts(normalize=True).sort_index().groupby(
            lambda x: strata[0] if x <= 6 else strata[1] if x <= 12 else strata[2]
        ).sum() for e in epochs
    ], axis=1, sort=True
```

(continues on next page)

(continued from previous page)

```
)

df.columns = epochs.keys()
df = df.reindex(strata)
df.T.plot(kind="bar", stacked=True, figsize=(12,5))
# plt.title("Epochs")
plt.legend(bbox_to_anchor=(1.3,0.75))
plt.gca().set_xticklabels(epochs.keys(), rotation="horizontal")
plt.tight_layout()
# plt.savefig("img/epochs_regions.png")
plt.show()
```



- Renaissance: largest diatonic proportion overall but mostly chromatic
- Baroque: alost completely chromatic
- Classical: enharmonic proportion increases -> more distant modulations
- This trend continues through the Romantic eras

8.7 Summary

1. We have analyzed a very specific aspect of Western classical music.
2. We have used a large(-ish) corpus to answer our research question.
3. We have operationalized musical pieces as vectors that represent distributions of tonal pitch-classes.
4. We have used the dimensionality-reduction technique Principal Component Analysis (PCA) in order to visually inspect the distribution of the data in 2 and 3 dimensions.
5. We have used music-theoretical domain knowledge to find meaningful structure in this space.
6. We have seen that pieces are largely distributed along the line of fifths.
7. We have used Locally Weighted Scatterplot Smoothing (LOWESS) to estimate the variance in this historical process.
8. We have seen that, historically, composers explore ever larger regions on this line and that the variance also increases.
